The surface of heteroepitaxial silicon grown on sapphire substrates exhibits a haze-like appearance. It has been noted that device yield and performance can be correlated with the degree and extent of haze observed on the silicon. Considerable effort has therefore been expended on developing quantitative optical procedures for the assessment of haze. Little has been reported on work aimed at establishing the structural origin of haze.

This contribution describes recent results on the determination of twin concentrations in hetero-epitaxial silicon. Details of the instrumentation employed will be given. It is shown that a correlation exists between twin concentrations and the determination of twin concentrations in hetero-epitaxial silicon. Considerable effort has therefore been expended on identifying and characterizing these twin concentrations.
