approximant [4] and the Hume-Rothery mechanism for the formation of the quasicrystal [5]. For Al-Co-Ni, Ni and Co are located in the most inner and second inner parts, respectively, of the columnar model cluster, indicating the tendency of the close distribution of Ni atoms and the separated distribution of Co atoms. This is consistent with a recent study on the formation of the quasiperiodic Al-Co-Ni surfaces by the scanning tunneling microscopy [6]. The chemical bond and formation of the quasicrystals has been discussed in terms of local clusters around the transition metals.

MM: Molecular Modelling DFT: Density Functional Theory Heterocyclic thiosemicarbazone and their metal complexes are among the most widely studied compounds for their potential antitumoral, antibacterial and antifungal activities (1). Some of these activities are closely related to the stability of molecular geometry (2) and especially when these activities are enhanced by the presence of some metallic ions (3). Therefore we were interested in single X-ray Crystallographic studies of some Ni(II) thiosemicarbazone complexes. These studies were supplemented by theoretical calculations (MM and DFT) in order to investigate more about the transmission of electronic effects between the redox unit and a metal center.

Prediction and experimental determination of the crystal structure of SiBr₄
Alexandra K. Wolf¹, Juergen Glinnemann¹, Martin U. Schmidt¹, Jianwei Tong², Robert E. Dinnebier², Arndt Simon², Juergen Koehler²

The crystal structure of SiBr₄ is unknown hitherto, although the structures of all other EX₄ compounds (with E = C, Si, Ge, Sn, Pb and X = F, Cl, Br, I) are published. Possible crystal structures of SiBr₄ were predicted with force-field methods using the program CRYSCA¹. Low-energy structures were post-optimised using the program package Cerius². All calculations were performed with a Dreiding/X6 force-field which was modified for Si-Br bond lengths. Calculations were performed in those space groups statistically most frequent for molecular compounds and for EX₄ compounds resp. P1 (Z = 1), P-1 (Z = 2), P2₁ (Z = 2), Cc (Z = 4), P2₁/c (Z = 4), P2₁/2₁/2 (Z = 4), Pna2₁ (Z = 4), Pca2₁ (Z = 4) and Pba (Z = 8). In many cases higher symmetries (supergroups) were reached during the optimisation. Several possible polymorphs were found within an energy range of 5 kJ/mol above the global minimum. X-ray powder diagrams of SiBr₄ revealed the existence of two polymorphs; their structures were determined from X-ray powder data: the cubic high temperature phase crystallises in Pa-3 (Z = 8), the low temperature phase in P2₁/c (Z = 4). Both phases had been predicted in the calculations.

Magnetic diffuse scattering is observed in the paramagnetic state or in frustrated magnetic systems where long-range order is impeded by geometric constraints. This diffuse scattering can easily be probed using neutron diffraction and single crystal diffraction in particular allows to obtain very detailed maps in reciprocal space. The amount of information available from reciprocal space surveys of magnetic diffuse scattering can potentially give detailed insight into the interaction between the magnetic ions. Yet, very few such studies have been carried out likely due to the lack of software tools, methodology or computational resources. Here, we present Monte-Carlo simulations on model systems supported by experimental data. This allows phase diagrams to be explored and the effect of varying exchange constants to be simulated. Furthermore, experiments of this type are currently performed on a few magnetic materials. A crucial aspect is the exact determination of powder patterns that are available using e.g. TEM images.
