Solid-state dynamic properties contribute to development of gas sorption and storage materials with microporous coordination polymers. Organic crystals function as dynamic materials due to their flexibility and diversity. We study on steroidal bile acid derivatives which serve as host components and form dynamic inclusion crystals for intercalation and enantioresolution of guest molecules. So far, we reported that cholamide has various types of flexible bilayers where secondary aliphatic alcohols are accommodated. Among them, 2,2-dimethyl-3-hexanol induces a rare bilayer structure which is responsible for high enantioselectivity. Here we present intercalation and enantioresolution of 2,2-dimethyl-3-hexanol by using inclusion crystals of cholamide with 1,4-dioxane. It was found that guest exchanges took place with retention of the crystalline state in appearance. The crystal structures were determined before and after the intercalation by means of powder X-ray diffraction, indicating that the intercalation accompanied layer inversion on the lipophilic sides of the bilayers. Moreover, it was found that the resulting crystals include (S)-2,2-dimethyl-3-hexanol in over 95% ee yield.

Structure and polymorphism of trans mono-unsaturated triacylglycerols
Henk Schenk, Jan B. van Mechelen, Rene Peschar
University of Amsterdam, Crystallography, HIMS, FNWI, Valckenierstraat 65, Amsterdam, NoordHolland, 1018XE, The Netherlands, E-mail: h.schenk@uva.nl

Trans fats are in a natural way in small quantities present in animal foods. Moreover, unsaturated plant fats are often partially hydrogenated to raise melting temperatures for preparation of foods, and then, as a minor side reaction, a small part of the cis-bonds will change into trans-configuration. Like saturated fats, fats with trans fatty acid residues will have negative effects for human health (1). The presence of the elaidoyl chain, one of the major trans fatty-acid chains, is suspected of increasing health risks because it resembles the stearoyl chain. When incorporated in biological membranes elaidoyl chains will be influencing the physical-chemical properties of the membranes. Thus insight in the influence of the differences between the fatty-acid composition of trans and saturated triacylglycerols (TAGs) on the conformation and packing, on polymorphic stability, and on phase-transition behavior, will be useful. By combining X-ray powder diffraction (XRPD) techniques a better understanding of trans mono-unsaturated TAGs and their related saturated ones can be obtained. Synchrotron and advanced laboratory time- and temperature-resolved XRPD reveal the stability and phase-transition behavior of the important polymorphs like the β' phase. These results can be related to the underlying crystal structure packing that can be obtained from XRPD data using direct-space search techniques. Our recent results will be discussed including novel meta-stable β' polymorphs and the structure of one them, methyl-end plane packing analysis in relation of observed melting points for various subgroups of TAGs, and the difference in β' to β phase-transition behaviour of symmetric versus asymmetric TAGs.

Enantioselective inclusion of methyl phenyl sulfoxides by (S)-alkylglycyl-(S)-phenylglycine
Motohiro Akazome, Ai Doba, Katsuyuki Ogura
Graduate School of Engineering, Chiba University, Department of Applied Chemistry and Biotechnology, 1-33 Yayoicho, Inageku, Chiba, Chiba, 263-8522, Japan, E-mail: akazome@faculty.chiba-u.jp

As dipeptide host molecules, (S)-alkylglycyl-(S)-phenylglycines were examined in terms of enantiomeric inclusion for racemic methyl phenyl sulfoxides. Among them, (S)-leucyl-(S)-phenylglycines (LeuPhg) and (S)-isoleucyl-(S)-phenylglycines (IlePhg) mainly included S-form of methyl phenyl sulfoxides with high enantioselectivity. By single crystal X-ray analyses of these inclusion compounds, it was elucidated that the dipeptide molecules self-assembled to form layer structures and included the sulfoxides between these layers by hydrogen bonding between the proton of ‘NH3’ and the oxygen of the sulfoxide. In the cavity, C-terminal phenyl group of the dipeptide interacts with the phenyl group of sulfoxides. In addition to these host-guest interactions, the two homochiral sulfoxides belonging in upper and lower layers make a pair having 2-fold rotation axis or 2-fold screw axis along the channel cavity. In other words, the self-recognition of sulfoxides made a homochiral pair to achieve high enantioselectivity.

Polymorphism and structure solution from powder data of N,N'-1,4-phenylene-bis(3-oxobutanamide)
Juergen Bruening, Edith Alig, Jan W. Bats, Jacco van de Streek, Martin U. Schmidt
Johann Wolfgang Goethe-University, Institute of Inorganic and Analytical Chemistry, Max-von-Lau-Str. 7, Frankfurt am Main, Hessen, 60438, Germany, E-mail: bruening@chemie.uni-frankfurt.de

N,N'-1,4-Phenylene-bis(3-oxobutanamide) (1) is an industrial intermediate which is used as a coupling component in the synthesis

C391
of organic azo pigments; it serves as a linker between two azo moieties [1]. Despite of its commercial importance, crystal structures of I are not known up to now. We were able to grow crystals from 1-butanol using re-crystallisation techniques. The X-ray structure analysis showed that the crystal was a monohydrate of I. We dried the powder of I at 120°C and measured its X-ray powder pattern. The powder was monomorphous and we were able to determine the structure from the powder pattern using DASH [2] and TOPAS [3]. This polymorph turned out to be the anhydrous form. A third polymorphic form was obtained by drying the mono-hydrate at 70°C. The resulting powder pattern contained eight reflexions only, and the crystal structure could not be solved yet.

Social insects distinguish their nest mates from aliens via the recognition pheremones that are part of the complex mixture of waxy chemicals found on the cuticle. Among these, methyl-branched alkanes appear to act as pheremones, whereas straight-chain alkanes do not. Thus the stereochemistry associated with the methyl group, or the conformation of the molecule imposed by this group, may affect the binding of the molecule to the receptors in an insect’s antennae. Enantiomerically pure methyl-branched alkanes have been synthesised and their crystal structures determined by high resolution powder diffraction, or by single crystal diffraction, using synchrotron radiation. 11-methyl nonacosane and 7-methylnonacosane are both monoclinic, space group P21/c, Z = 2, a = 15.582 Å, b = 7.144 Å, c = 14.096 Å, β = 114.913° and a = 28.172 Å, b = 4.935 Å, c = 10.375 Å, β = 90.3°, respectively. The two compounds have distinct molecular packing arrangements in the structure. Moreover, molecules in 11-methylnonacosane are very straight, whereas 7-methylnonacosane molecules show a slight bend in the chain near the methyl group.

Five alternative crystal forms produced by crystallisation of a simple alicyclic dialcohol

Roger Bishop, Vi T. Nguyen, Donald C. Craig, Marcia L. Scudder
The University of New South Wales, School of Chemistry, University of New South Wales, Sydney, New South Wales, 2052, Australia, E-mail: r.bishop@unsw.edu.au

The simple racemic dialcohol I formed inclusion compounds in all recrystallisation experiments attempted by us. Many of these crystals are isostructural clathrates of stoichiometry 3(host).1(guest) that are formed in the cubic space group Ia3. However, two further inclusion crystal forms are also produced, namely 6(host).1(p-xylene) and 2(host).1(water), from these specific solvents. If the cubic crystals are sublimed, then the guest molecules are lost and solvent-free apohost crystals are formed instead in the monoclinic space group P21/c. Finally, resolved I crystallises solvent-free in the tetragonal space group P4,22 (or its enantiomorph). All of these five very different crystal forms utilise different hydrogen-bonded supramolecular synthons to create their structures. These arrangements will be described and contrasted. In particular, it will be argued that the most common cubic crystal form is a supramolecular cousin of the well-known host Dianin’s compound, despite the very different molecular structures of the two compounds.

1H NMR application to inclusion chemistry: Selectivity profiles of a xanthenol-related host

Gaelle Ramon1, Luigi R Nassimbeni2, Jana H Taljaard3
1Cape Peninsula University of Technology, Applied Sciences, PO Box 652, Cape Town, Western Cape, 8000, South Africa, 2Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa, 3Department of Chemistry, Nelson Mandela Metropolitan University, 6031, South Africa, E-mail: gaeller@cup.ac.za

10,11-Dihydro-5-(1-naphthyl)-5H-dibenzo[a,d]cyclohepten-5-ol (H) is a derivative from the xanthenol family. We obtained its alpha-structure by recrystallisation at room temperature in ethanol. Subsequently, we crystallised it at room temperature from pyridine (Pyr), 1,4-dioxane (Diox) and DMSO. In all cases, we obtained 1:1 host-guest inclusion compounds displaying hydrogen bonding between the host and the guest molecules. The three structures belong to very different space groups (C2/c, P-1 and P21/c respectively for pyridine, 1,4-dioxane and DMSO) which was interesting to consider when carrying out competition experiments between the solvents with H. We characterized the selectivity profile of our host H with the three solvents using 1H NMR. We have carried out competition experiments between pairs of guest molecules and characterized the ensuing inclusion compounds formed. We rationalise the structural results with the molecular properties of the guests in terms of their donor/acceptor capacities.
