Complexes of para disubstituted and 4-monosubstituted biphenyl formed with 4,4’-dinitrobenzophenyl (DNBP), demonstrate intense colours, from pale yellow to dark red, upon formation. These colours are dissimilar to the colour combination of the parent compounds. The focus of this study was to investigate the nature of these molecular donor-acceptor interactions in the solid state, using spectroscopic techniques such as IR, Raman, UV-Vis, NMR and X-ray crystallography. Typical interactions observed in such molecular complexes include π-π interactions, hydrogen bonding, charge transfer and van der Waals interactions. There are no significant localized interactions between the guest molecule and the DNBP, except for the weak H-bond observed in the hydroxybenzophenyl complex [1]. Complexes of DNBP, as acceptor, studied included a variety of mono- and disubstituted donors, such as dihalo, diamino, di- and monohydroxy groups. The crystal structures of these complexes showed retention of the non-planar conformation of DNBP with a dihedral angle of around 35°. This conformation for DNBP has also been confirmed using density functional theory (Gaussian) calculations that showed good agreement between the theoretically calculated and experimentally observed IR and Raman spectra in the solid state. In non-complexed DNBP, adjacent stacks of DNBP molecules form a herring-bone pattern when viewed from above. On forming complexes with planar guest molecules, the stacks open out to form a checker-board pattern (as viewed from above) forming slots between the stacks which are occupied by the guest molecules. The packing is generally similar in all the complexes with planar guest molecules and is determined by the stacking of the DNBP molecules - with the substituted biphenyls, urea [2] or thiourea guest molecules slotting in between the stacks. It appears as if the packing of the complexes in the solid state is directed mainly by the similar packing of DNBP units in these complexes. Some of the molecular ratios for these complexes that vary, depending on the electronic properties of the donor molecules, were determined using NMR spectroscopy. The ratio of guest to DNBP depends on the size (length) of the guest molecule.

Pheromones are widely recognised as being extremely important among social insects as a means of communication [1]. They can be both volatile and non-volatile chemicals, which can act by simple detection in the air or by direct contact, respectively. The pheromones that this study focuses on fall in the second category (“recognition pheromones”), and in particular on methyl branched alkanes. Whilst evidence suggests that methyl-branched alkanes have an effect as recognition pheromones, straight chain alkanes have regularly been shown to have no effect, despite having very similar chemical properties. This has led to the suggestion that the conformation of the compounds may have an effect which leads to the distinction. Previous theoretical calculations [2] have suggested that the lowest energy conformation of a methyl-branched alkane is a “paperclip” conformation. In this study three enantiomerically pure methyl-branched alkanes were investigated, namely 11-methyl nonacosane C29Me(11), 9-methyl nonacosane C29Me(9) and 11-methyl heptacosane C27Me(11). Their structures were derived from high resolution X-ray powder diffraction data and subsequently optimized by a geometry optimization by energy minimization in solid state using DFT approach. The aim is to attempt to ascertain how the stereochemistry associated with the methyl group, or the conformation of the molecule imposed by this group, may affect the binding of the molecule to the receptors in an insect’s antennae.
Experimental and Theoretical Investigation of the Molecular and Electronic Structure of N-Cyclohexyl-2-(5-(4-pyridyl)-4-(p-tolyl)-4H-1,2,4-triazol-3-ylsulfanyl)acetamide Dihydrate.

1,2,4-triazoles and its derivatives represent one of the most biologically active classes of compounds, possessing a wide spectrum of activities including antibacterial, antifungal, antiviral, anti-inflammatory, anticancer, antidepressant, antihypertensive, analgesic, and hypoglycemic properties [1]. In addition, substituted 1,2,4-triazoles have been actively studied as bridging ligands in metal complexes, particularly in hypoglycemic properties [1]. In addition, substituted 1,2,4-triazoles have been actively studied as bridging ligands in metal complexes, particularly in hypoglycemic properties [1].

In the crystal structure of the title compound [systematic name: diazabutadiene(6-methyl-2,2-dioxo-1,2,3-oxathiazine-4,4-dione)]bis(3-methylpyridine-κN)nickel(II), NiII(µ-PPh2)₂(C6H4NO4)₂, the NiII centre resides on a centre of symmetry and has a distorted octahedral geometry. The basal plane is formed by two carbonyl O atoms of two monodentate trans-oriented acetate ligands and two trans aqua ligands. The axial positions in the octahedron are occupied by two N atoms of two trans pyridine ligands.

Molecules are stacked in columns running along the a axis. There are π–π stacking interactions between the molecules in each column, with a distance of 3.623(2) Å between the centroids of the pyridine rings. There are also O–O interactions between the columns.

Chemical Bonding and Electronic Configuration of Phosphido-bridged Mo and W Complexes.

Charge density and x-ray absorption spectroscopy (XAS) are applied to characterize the chemical bonding and electronic structures of the heterobimetallic phosphido-bridged complexes, CpW(CO)(µ-PPh3)Mo(CO)2 (1) with W-Mo distance 3.1723(4) Å and Cp(W(CO)(µ-PPh3)Mo(CO)2 (2) with W-Mo distance 4.510(4) Å. Both have been reported with special chemical reaction properties because of the interaction between W and Mo: complex 2 can be converted into 1 after irradiation with UV or heating at reflux temperature. In order to correlate how the chemical bond of Mo-W affect the chemical reaction in complex 1 and 2, the accurate single crystal diffraction data of both complexes at 100 K are collected and the experimental
