Ca$_{12}$Al$_{34}$O$_{33}$, also known as C12A7, consists of a positively charged cage-like structure with occluded anions occupying one out of every six cages to charge balance the positively charged framework. The occluded anion gives rise to the highly function nature of the material and raises questions about isostructural compounds and their potential properties. Framework distortions are correlated to changing the electrical properties from a wide band gap insulator to metallic conductor in electrode C12A7 systems so it is possible that alteration of Al cations in the electrode structure may lead to changes in physical properties. The existence of C12G7 has been theorized due to the similarity of the CaO-Al$_2$O$_3$ and CaO-Ga$_2$O$_3$ binary phase diagrams, however, attempts to synthesize C12G7 through solid state techniques has only resulted in formation of the CSG3 phase [1]. Using wet chemistry techniques single phase C12G7 has been successfully synthesized. X-ray powder diffraction data of the C12G7 has been collected and analyzed using the Rietveld method. The refined lattice parameter for C12G7 is 12.2991(3) Å, approximately 2.5% larger than the lattice parameter of C12A7.
