Supplementary Figure S1. The relationship between top SPICKER cluster size and the success or failure of MR attempts on derived search models.

Supplementary Figure S2. Examples of how progressive truncation of ensembles results in reductions of the rmsd values of the resulting structural cores with respect to experimental crystal structures. The rmsd values are measured for search models post-MR, with both PHASER and MOLREP, and after brief refinement in REFMAC. Search models for targets 1G6U and 1R6J are shown with ultimately successful solutions shown in black. Success is not achieved until inaccurate regions have been removed.

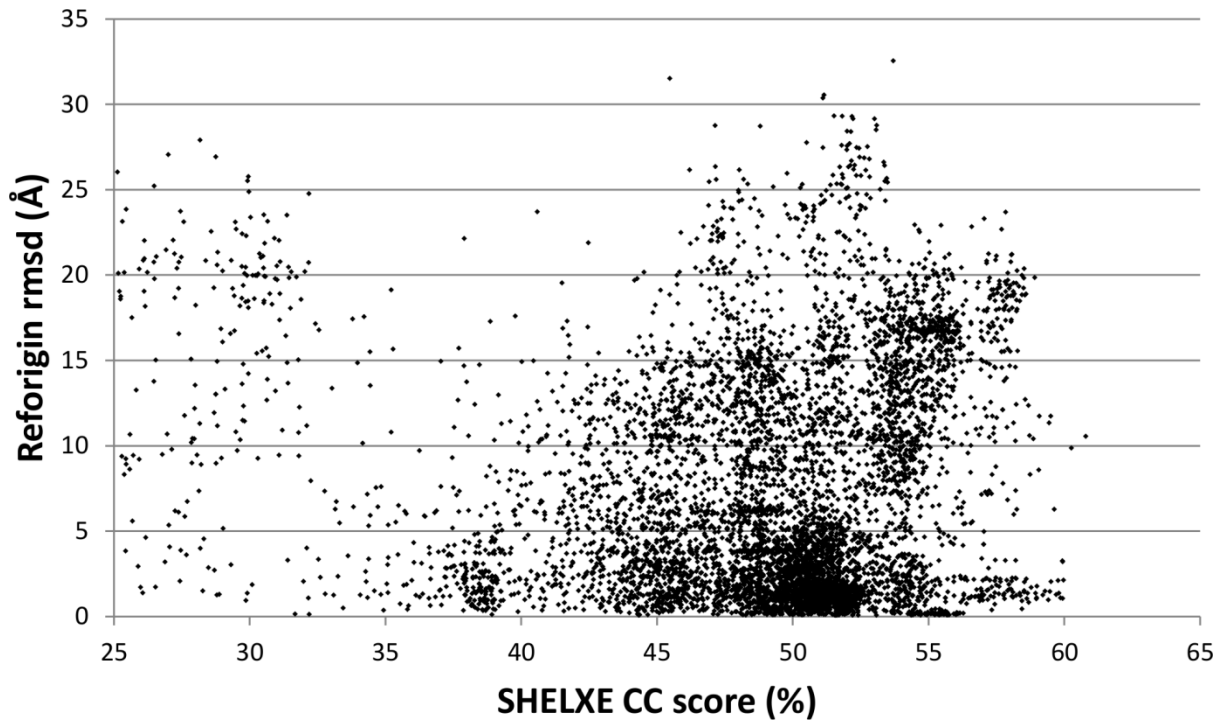

Supplementary Figure S3. Distribution of SHELXE CC scores after density modification and main-chain tracing. The peak on the right with scores greater than 25% contains correct solutions that can be automatically traced.

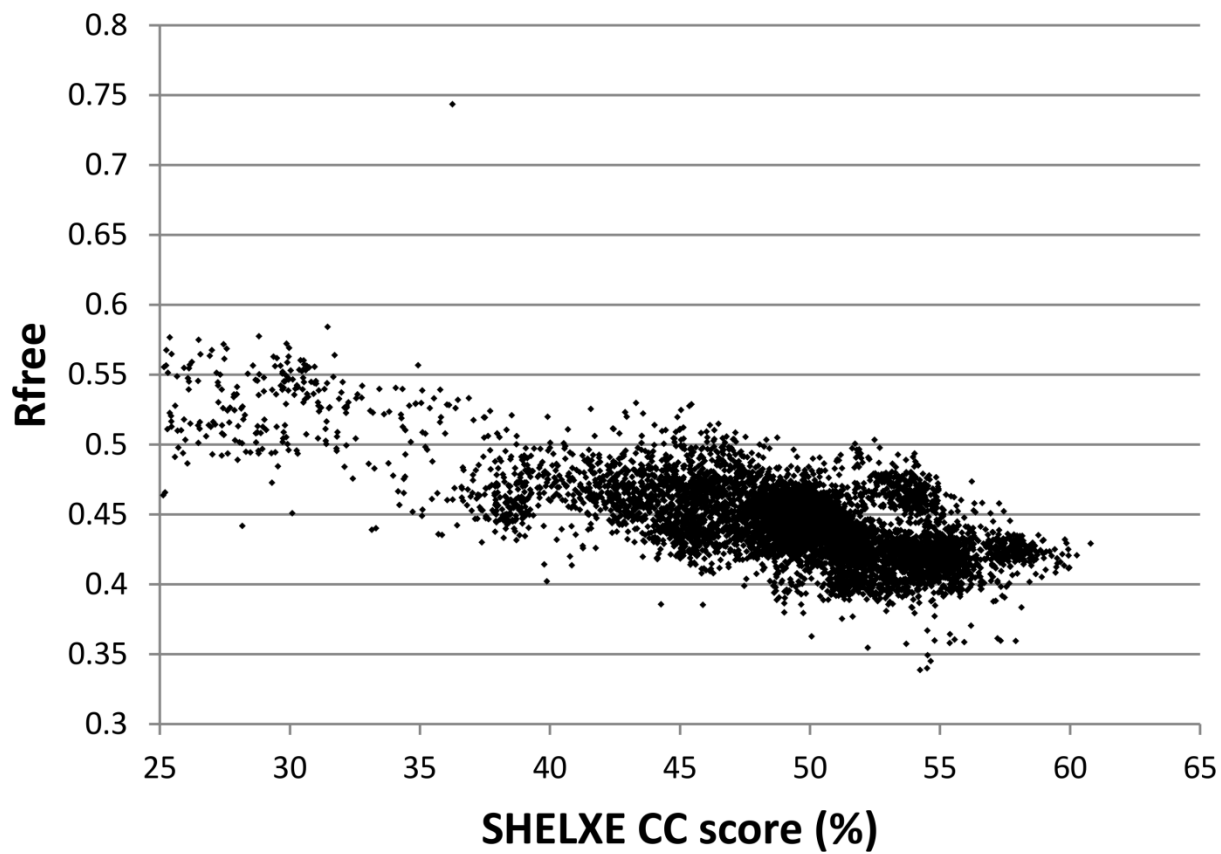

Supplementary Figure S4. Relationships between a) SHELXE CC score and Reorigin rmsd, b) SHELXE CC score and Rfree and c) rmsd error of model and Reorigin *rmsd* for successful search models. a) illustrates that, as expected, accurate placement of the search model is generally required for success, although in a surprisingly large number of cases wholly inaccurate placement that resulted in the fortuitous matching of some secondary structure elements yielded sufficient phasing power for refinement. c) indicates that successes from inaccurate placement arise for both accurate and inaccurate models.

Supplementary Figure S5. Phaser TFZ scores for successful and unsuccessful search models.

The failures in the most populated bins number 2961 (TFZ 2-3), 12081 (3-4), 17956 (4-5) and 5636 (5-6).

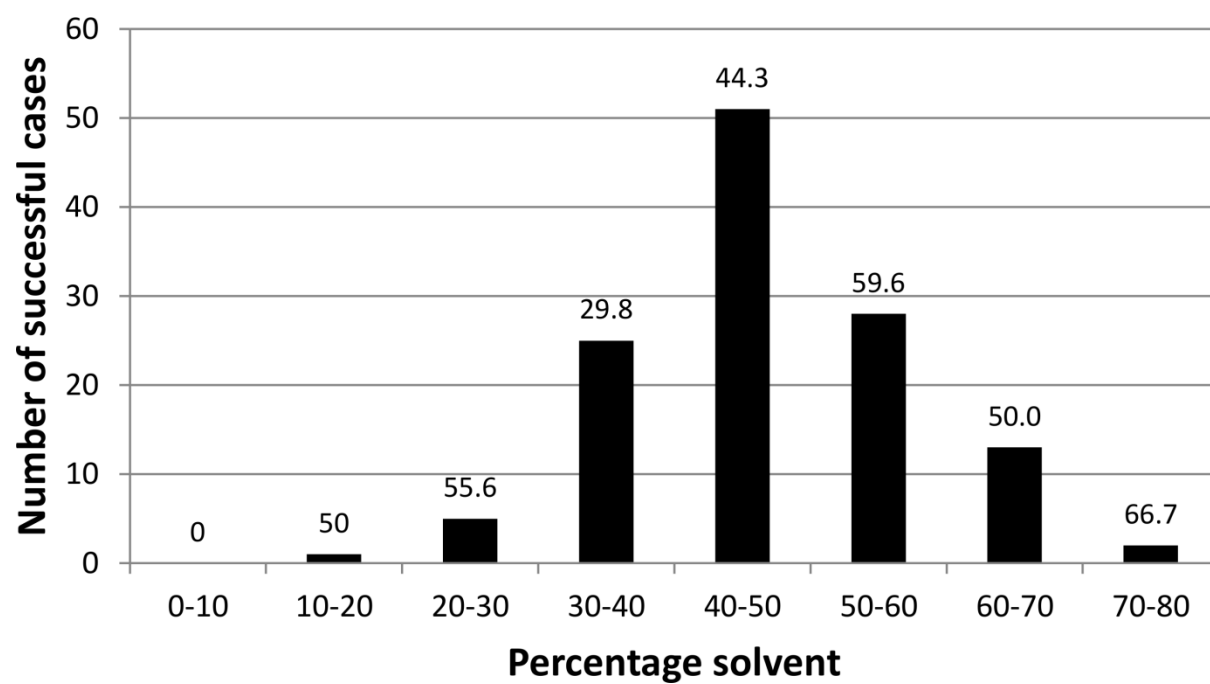

Supplementary Figure S6. All- α targets are more accurately modelled than all- β targets, with mixed α - β targets intermediate. The bar charts show, for each fold class, the mean GDT score of the best decoy produced by ROSETTA for each target.

Supplementary Figure S7. The crystal system of the target structure has little influence on success. Bars show numbers of successful cases in each category topped by the % of targets that were successful.

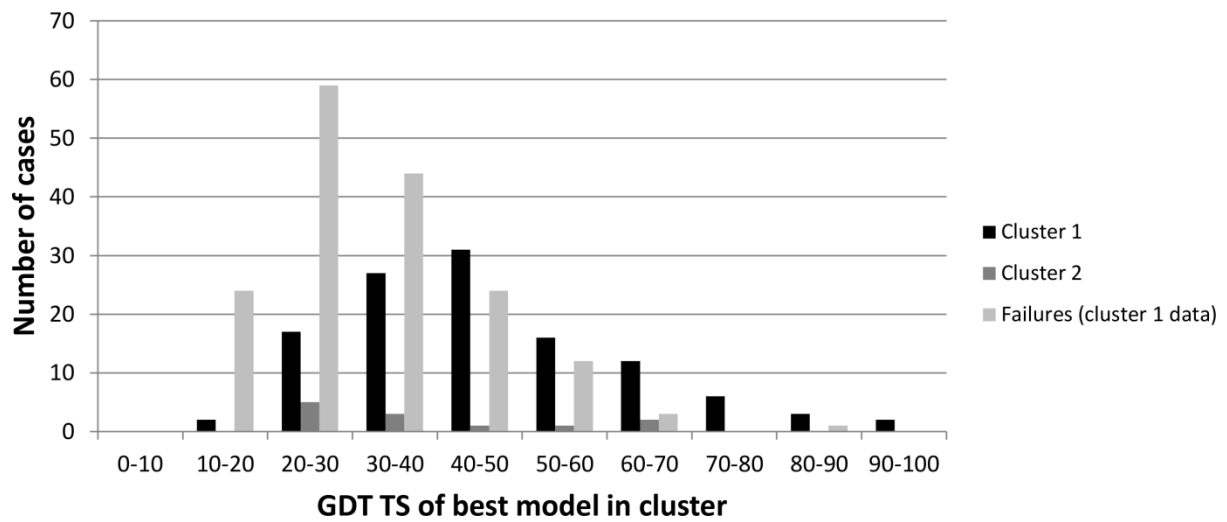

Supplementary Figure S8. The % solvent content of target crystal structure has little influence on success. Bars show numbers of successful cases in each range topped by the % of targets that were successful.

Supplementary Figure S9. In the range covered here, the high resolution limit of the diffraction data appears to have little influence on success. Bars show numbers of successful cases in each range topped by the % of targets that were successful.

Supplementary Figure S10. Success is more likely when the initial SPICKER clusters contain decoys with a GDT score of greater than 40 i.e. with an approximately correct overall fold. Black bars are cases where search models deriving from SPICKER cluster 1 were successful. Dark grey shows cases that solved with cluster 2 but not cluster 1. Scores for cluster 1 of failing targets are shown in light grey.

Supplementary Figure S11. Representative examples of accurately modelled ensembles of different sizes that successfully solved their targets. a) a 4 residue (5%) fragment of target 1ZZK with rmsd error 0.14 Å and reforigin value of 3.3 Å, b) a 31 residue (40%) region of 1USM (rmsd 0.7 Å, reforigin 0.8 Å) and c) a full-length, 116 residue model ensemble of 3MXZ (rmsd 5.7 Å, reforigin 6.3 Å). In each case the target is shown coloured blue to red, from N- to C-terminus, and the search model shown in pink.

a)

b)

c)

Supplementary Figure S12. Examples of successes arising from inaccurately modelled and/or inaccurately placed search models. Such cases occur predominantly for targets with long α -helices. a) target 1GK6 with rmsd error 21.3 Å and reorigin value of 26.0 Å, b) 3EFG (rmsd 16.6 Å, reorigin 19.1 Å), c) 2ZQM (rmsd 2.3 Å, reorigin 29.3 Å) and d) 1WPA (rmsd 2.1 Å, reorigin 26.0 Å). Colouring is as in Figure S11
