## 2-C-Methyl-D-lyxono-1,4-lactone

The title compound, $\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{5}$, has been crystallized for the first time, allowing the stereochemistry at C-2 and the ring size of the lactone to be firmly established.

## Comment

The Kiliani ascension of ketoses (Hotchkiss et al., 2004; Soengas et al., 2005) provides ready access to a new class of branched carbohydrate scaffolds (Lichtenthaler \& Peters, 2004; Bols, 1996) with branched carbon chains. Although saccharinic acids, which are $2-C$-methyl aldonic acids, are formed in very low yields from treatment of aldoses or ketoses with aqueous calcium hydroxide (Whistler \& BeMiller, 1963), it has been shown that significantly higher yields may be obtained from the reaction of lime with ketoses (Hotchkiss et al., 2006) derived from the Amadori rearrangement (Hodge, 1955). D-Galactose reacted with dibenzylamine to form the Amadori ketose, (2) (Grunnagel \& Haas, 1969), in which the $\alpha$-configuration at the anomeric position of the pyranose ring has been proved by X-ray crystallographic analysis (Harding et al., 2005). Treatment of (2) with aqueous calcium hydroxide allowed the isolation of a mixture of two epimeric lactones.

(1)
(2)

(3)

(4)

The structure of the minor isomer was confirmed as $2-C$ -methyl-D-xylono-1,4-lactone, (3), by an X-ray structure of its 3,5-acetonide (Watkin et al., 2005). The major product, 2-C-methyl-d-lyxono-1,4-lactone, (4), initially isolated as an oil, slowly crystallized, allowing the relative configuration at C-2 and the ring size of the lyxonolactone to be unambiguously assigned by X-ray crystallographic analysis.

Racemic lactone (4) has only been obtained as an oil (Lopez et al., 1984); the enantiomer of (4) has been prepared in low yield from l-sorbose (Ishizu et al., 1972). The absolute configuration of (4) was determined from the use of D-galactose (1) as the starting material.

## Experimental

The lactone (4) \{m.p. 379-380K, $[\alpha]_{\mathrm{D}}{ }^{23}+70.4$ (c 0.87 in acetone) $\}$ was crystallized by dissolving it in acetone and allowing the slow evaporation of the solvent until colourless block-shaped crystals formed. The multi-scan technique was used to correct for changes in the illuminated volume.

## S1. Comment

The Kiliani ascension of ketoses (Hotchkiss et al., 2004; Soengas et al., 2005) provides ready access to a new class of branched carbohydrate scaffolds (Lichtenthaler \& Peters, 2004; Bols, 1996) with branched carbon chains. Although saccharinic acids - which are 2-C-methyl aldonic acids - are formed in very low yields from treatment of aldoses or ketoses with aqueous calcium hydroxide (Whistler \& BeMiller, 1963), it has been shown that significantly higher yields may be obtained from the reaction of lime with ketoses (Hotchkiss et al., 2006) derived from the Amadori rearrangement (Hodge, 1955). d-Galactose reacted with dibenzylamine to form the Amadori ketose (2) (Grunnagel \& Haas, 1969), in which the $\alpha$-configuration at the anomeric position of the pyranose ring has been proved by X-ray crystallographic analysis (Harding et al., 2005). Treatment of (2) with aqueous calcium hydroxide allowed the isolation of a mixture of two epimeric lactones.
Table 1.
The structure of the minor isomer was confirmed as 2-C-methyl-d-xylono-1,4-lactone (3) by an X-ray structure of its 3,5-acetonide (Watkin et al., 2005). The major product 2-C-methyl-d-lyxono-1,4-lactone (4), initially isolated as an oil, slowly crystallized allowing the relative configuration at C-2 and the ring size of the lyxonolactone to be unambiguously assigned by X-ray crystallographic analysis.
Figure 1.
Racemic lactone (4) has only been obtained as an oil (Lopez et al., 1984); the enantiomer of (4) has been prepared in low yield from $l$-sorbose (Ishizu et al., 1982 or 1972). The absolute configuration of (4) is determined from the use of dgalactose (1) as the starting material.

Figure 2.

## S2. Experimental

The lactone (4) (m.p. 379-380 K, $[\alpha]_{\mathrm{D}}{ }^{23}+70.4$ (c 0.87 in acetone)) was crystallized by dissolving it in acetone and allowing the slow evaporation of the solvent until colourless block-shaped crystals formed. The multi-scan technique was used to correct for changes in the illuminated volume.

## S3. Refinement

Because the data were collected with molybdenum radiation, there were no measurable anomalous differences, as a consequence of which it was admissible to merge Friedel pairs of reflections. H atoms were seen in a difference density synthesis. Those attached to C atoms were repositioned geometrically. The H atoms were initially refined with soft restraints on the bond lengths and angles to regularize their geometry $(\mathrm{C}-\mathrm{H}=0.96-0.98, \mathrm{O}-\mathrm{H}=0.81-0.88 \AA)$, after which they were refined as riding, with $\mathrm{U}(\mathrm{H})=1.2 U_{\mathrm{eq}}(\mathrm{C})$ for those bonded to carbon, and $\mathrm{U}(\mathrm{H})=0.05 \AA^{2}$ for the hydroxy group.

Figure 1
The asymmetric unit of (4), with displacement ellipsoids drawn at the $50 \%$ probability level. H -atom radii are arbitrary.

Figure 2
Packing diagram of (4), viewed down the $c$ axis. Hydrogen bonds are displayed with dashed lines.
