In the title inclusion compound, $2C_{24}H_{40}O_5 \cdot C_8H_6N_2$, the unit cell contains two molecules of cholic acid ($3\alpha,7\alpha,12\alpha$-trihydroxy-5β-cholan-24-oic acid) and one molecule of quinoxaline which implies disorder of the quinoxaline in the space group $P2_1$. The amphiphilic molecules of cholic acid assemble, in an antiparallel arrangement, via O—H···O hydrogen bonds, into typical corrugated host bilayers which are lipophilic on the outside and lipophobic on the inside. The host framework belongs to the so called α-trans subtype. The quinoxaline molecules are accommodated in lipophilic channels formed between neighboring bilayers with only van der Waals interactions between host and guest. There is a crystallographic twofold screw axis directed along an empty channel in the host framework; however, neighboring guests in any one channel are related by a unit-cell translation along the b axis. Thus, the overall structure is a 1:1 superposition of two such channels related by the crystallographic twofold screw axis.

supporting information

Cholic acid–quinoxaline (2/1)

Barbara Wicher and Maria Gdaniec

S1. Comment

Cholic acid forms inclusion compounds with a large variety of guest molecules (Miyata & Sada, 1996). The host framework is strongly dependent on the guest but, in most cases, it is constructed from cholic acid bilayers which are lipophilic on the outside and lipophobic on the inside (Nakano *et al.*, 2001, 2006). The type of the host framework and the host:guest ratio are strongly dependent on the volume and shape of the guest (Nakano *et al.*, 2001). In the case of bilayers with an antiparallel arrangement of host molecules, four framework subtypes are generally recognized: *α-gauche*, *α-trans*, *β-gauche* and *β-trans* (Miyata & Sada, 1996) based on the conformation of the steroidal side chain (*gauche/trans*) and the stacking mode of the bilayers (*α/β*). Among numerous guest molecules that have cocrystallized with cholic acid no larger arenes or aromatic azaheterocycles have been reported. This is probably due to the problems with accommodating large molecules of fixed geometry within corrugated host channels. Quinoxaline easily cocrystallized with cholic acid, because as a low melting solid it could be used for cocrystallization without the need for any additional solvent.

   In (I) (Fig. 1), the host molecules are arranged in typical antiparallel bilayers and the framework can be classified as *α-trans* (Fig. 2). Four molecules of the host generate a cyclic motif of O—H···O hydrogen bonds (Fig. 3, Table 1) that assembles molecules into a two-dimensional polymeric structure (host bilayer). The hydrogen bonds are not completely buried on the inside of the bilayer as they partially line the grooves on the corrugated bilayer surface. The quinoxaline molecules are accommodated in lipophilic channels formed between neighboring bilayers and there are only van der Waals interactions between host and guest. The unit cell contains two molecules of the bile acid and one molecule of quinoxaline. In $P2_1$ this implies disorder of the guest and this is the case for (I): the crystallographic symmetry of the empty channel is higher than the symmetry of the guest arrangement within the channel. Neighbouring guests are related by translation along *b* [7.8968 (3) Å] and not by the crystallographic 2_1 axis operating along the channel (Fig. 4). There is no long-distance order in the channels because no reflections in addition to the Bragg reflections were detected. Thus, the model of the crystal structure of the title compound reveals superposition of two channels related by the crystallographic twofold screw axis (Fig. 4).

S2. Experimental

The title compound was obtained by dissolving cholic acid (0.1 g, 0.24 mmol) in melted quinoxaline (0.7 g, 5.38 mmol) and evaporation of the excess of quinoxaline at 60°C for two days. The resulting colorless plates were stable in air.

S3. Refinement

In the absence of significant anomalous scattering effects, Friedel pairs were averaged. The absolute configuration of cholic acid was assigned from the known configuration of the starting material. All H atoms were located in electron-density difference maps. For refinement all H atoms were placed at calculated positions, with C—H = 0.96–0.98 Å and O—H = 0.82 Å, and were refined as riding on their carrier atoms with $U_{iso}(H) = 1.2U_{eq}(C, O)$. No restraints were imposed

on geometry of the disordered quinoxaline molecules (occupancy factor 1/2).
Figure 1

The molecular structure of the title compound with displacement ellipsoids shown at the 50% probability level. H atoms bound to C atoms are omitted for clarity.
Figure 2

Crystal packing viewed down the *b* axis. Hydrogen bonds are shown with dashed lines.
Figure 3

Cyclic motif of O—H···O hydrogen bonds generating two-dimensional network of the host molecules.
Figure 4

Arrangement of the guest molecules within the channels. In the channels A and B the molecules are related by translation operation. The channel C shows superposition of the channels A and B (related by the twofold screw axis), as seen from the electron-density maps.

Refinement

Refinement on F^2	Secondary atom site location: difference Fourier map
Least-squares matrix: full	
$R[F^2 > 2\sigma(F^2)]$ = 0.035	Hydrogen site location: inferred from neighbouring sites
$wR(F^2)$ = 0.102	
S = 1.07	H-atom parameters constrained
2929 reflections	$w = 1/[\sigma^2(F_o^2) + (0.0726P)^2]$
353 parameters	where $P = (F_o^2 + 2F_c^2)/3$
1 restraint	$(\Delta/\sigma)_{max}$ = 0.004
Primary atom site location: structure-invariant direct methods	$\Delta\rho_{max}$ = 0.23 e Å⁻³
	$\Delta\rho_{min}$ = −0.17 e Å⁻³

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2, conventional R-factors R are based on F, with F set to zero for negative F^2. The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R-factors(gt) *etc*. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
