Received 24 April 2008; accepted 29 April 2008

Key indicators: single-crystal X-ray study;  $T = 150\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$ ;  $R$  factor = 0.044;  $wR$  factor = 0.124; data-to-parameter ratio = 10.4.

Addition of methyl lithium to D-erythro-1,4-lactone followed by acid deprotection was shown, by X-ray crystallography, to give 1-deoxy-D-arabinitol,  $\text{C}_5\text{H}_{12}\text{O}_4$ , rather than 1-deoxy-D-ribitol as the major product. The crystal structure exists as hydrogen-bonded chains of molecules running parallel to the  $c$  axis which are further linked together by hydrogen bonds. Each molecule is a donor and an acceptor for four hydrogen bonds. Each molecule is a donor and an acceptor for four hydrogen bonds.

## 1-Deoxy-D-arabinitol

**Sarah F. Jenkinson, Filipa P. Cruz, Kathrine V. Booth, George W. J. Fleet, Ken Izumori, Chu-Yi Yu and David J. Watkin**

### S1. Comment

The demand for the large scale production of rare sugars by biotechnological (Izumori, 2006; Izumori, 2002; Granstrom *et al.*, 2004) and chemical (Beadle *et al.*, 1992) methods is driven by the demand for alternative foodstuffs (Skytte, 2002) and D-tagatose itself is used as a low calorie sweetener (Levin, 2002; Howling & Callagan, 2000; Bertelsen *et al.* 1999). Rare monosaccharides have been found to demonstrate interesting pharmaceutical properties, for example, D-psicose (Takata *et al.*, 2005; Menavuviu *et al.*, 2006) and D-allose (Sui *et al.*, 2005; Hossain *et al.*, 2006) have significant chemotherapeutic properties and D-tagatose has been found to be an anti-hyperglycemic agent (Zehner *et al.*, 1994; Donner *et al.*, 1999) and therefore potentially useful in the treatment of diabetes.

The methodology developed by Izumori *et al.* (2002, 2006) for the interconversion of tetroses, pentoses and hexoses by enzymatic oxidation, inversion at C3 with a single epimerase, and reduction to the aldose has been seen to be generally applicable for the 1-deoxy ketohexoses (Yoshihara *et al.*, 2008). In order to investigate the viability of this process to the corresponding pentoses and thus to evaluate their therapeutic potential 1-deoxy-D-arabinitol was synthesized, in 3 steps, from 2,3-*O*-isopropylidene-D-erythronolactone **1** (Fig. 1). It has previously been seen that the four diastereomeric tetraols are very difficult to distinguish between by NMR spectroscopy (Takai & Heathcock, 1985). X-ray crystallography confirmed that the major product was the arabinitol **4** rather than the ribitol **3** which differs only in the stereochemistry at the C2 position (Fig. 2).

The molecules are linked by three hydrogen bonding systems and the structure consists of alternating spiral chains of O6—H6···O6 or O8—H8···O8 hydrogen-bonded molecules running parallel to the *c*-axis (Fig. 3) interconnected by O1—H1···O4—H4···O1 hydrogen bonds (Fig. 4). Each molecule is a donor and acceptor for 4 hydrogen bonds (Fig. 5).

In summary, the stereochemistry at C2 of the title compound 1-deoxy-D-arabinitol **4** was firmly established by X-ray crystallography, the absolute configuration is determined by the use of D-erythronolactone as the starting material. As well as the potential biological properties of 1-deoxy ketoses, they are likely to provide a new set of building blocks for the synthesis of a wide variety of complex biomolecules.

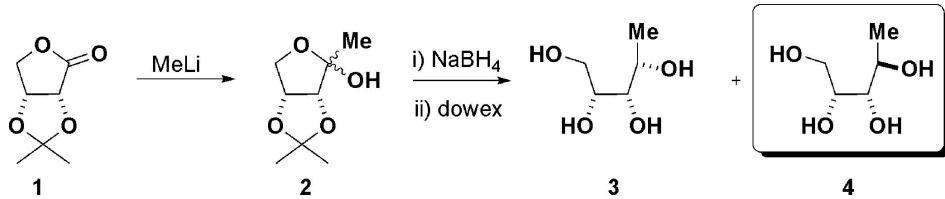

### S2. Experimental

The title compound was recrystallized from hot methanol: m.p. 398–400 K;  $[\alpha]_D^{21} +0.8$  (*c*, 8 in H<sub>2</sub>O) {Lit. (Zissis & Richtmyer, 1954) m.p. 129–131°C;  $[\alpha]_D^{20} +0.7$  (*c*, 10 in H<sub>2</sub>O; *l*, 4)}.

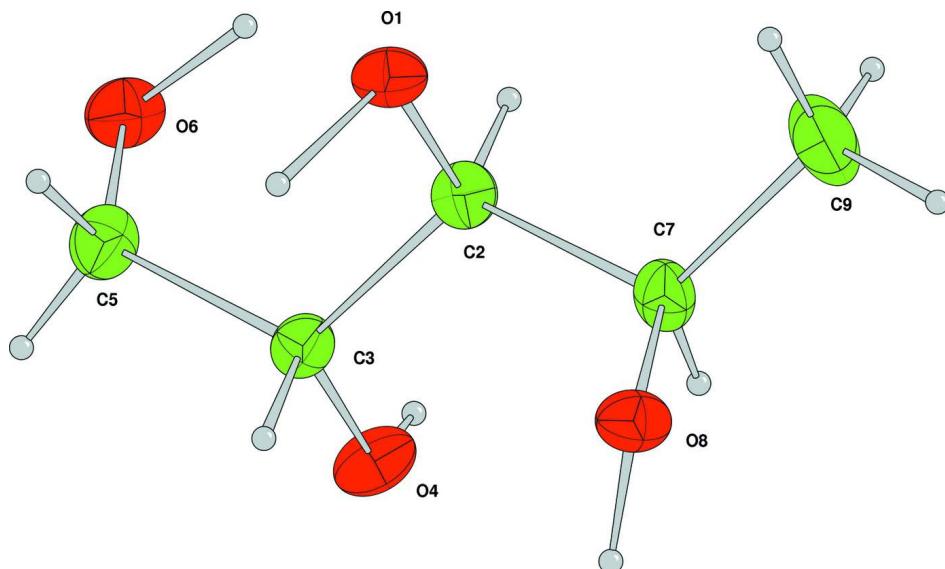

### S3. Refinement

In the absence of significant anomalous scattering, Friedel pairs were merged and the absolute configuration assigned from the starting material.

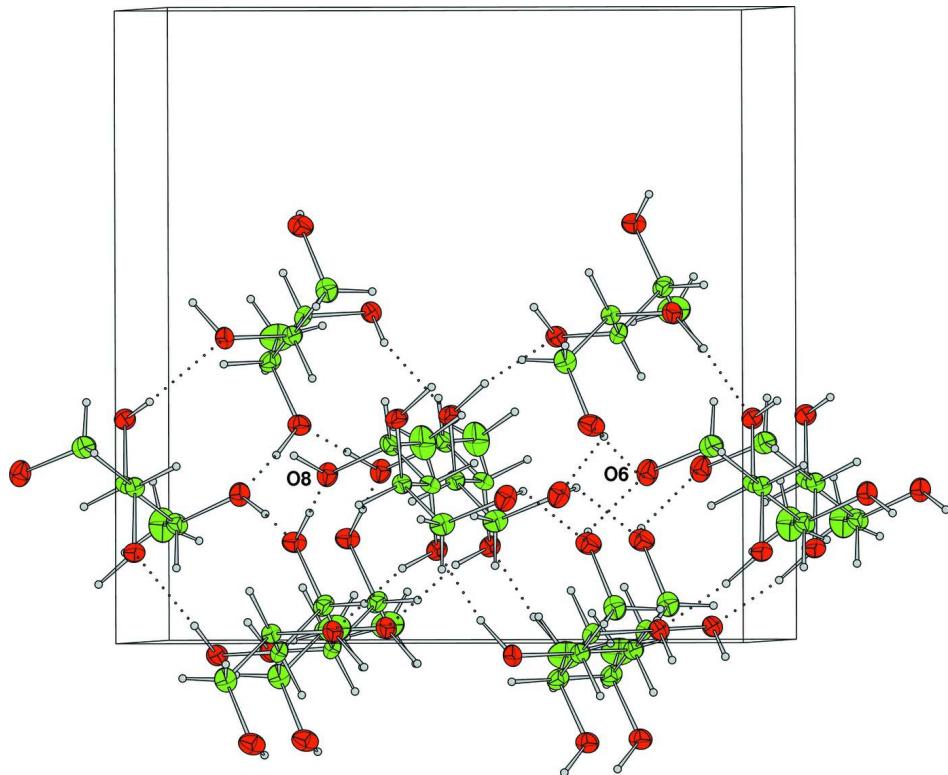

The H atoms were all located in a difference map, but those attached to carbon atoms were repositioned geometrically. The H atoms were initially refined with soft restraints on the bond lengths and angles to regularize their geometry (C—H in the range 0.93–0.98, O—H = 0.82 Å) and  $U_{\text{iso}}(\text{H})$  (in the range 1.2–1.5 times  $U_{\text{eq}}$  of the parent atom), after which the positions were refined with riding constraints.
