Received 1 July 2008; accepted 4 July 2008

Key indicators: single-crystal X-ray study;  $T = 100$  K; mean  $\sigma(C-C) = 0.003$  Å;  $R$  factor = 0.023;  $wR$  factor = 0.060; data-to-parameter ratio = 24.6.

In the title compound,  $C_{16}H_{14}NS^+\cdot I^-$ , the cation has an *E* configuration about the  $C=C$  double bond of the ethylene unit. The dihedral angle between the thiophene ring and the quinolinium ring system is  $11.67(11)^\circ$ . A weak  $C-H\cdots S$  intramolecular interaction involving the thiophene ring generates an *S*(5) ring motif. In the crystal structure, the iodide ion, located between the cations arranged in an antiparallel manner, forms weak  $C-H\cdots I$  interactions. The crystal structure is further stabilized by a  $\pi-\pi$  interaction between the thiophene and pyridine rings; the centroid–centroid distance is  $3.6818(13)$  Å.

## 1-Methyl-2-[*(E*)-2-(2-thienyl)ethenyl]quinolinium iodide

**Pumsak Ruanwas, Thawanrat Kobkeathawin, Suchada Chantrapromma, Hoong-Kun Fun and Chatchanok Karalai**

### S1. Comment

The design and synthesis of conjugated compounds to search for second-order nonlinear optic (NLO) materials have generated extensive interest. From previous reports, both molecular orbital calculations (Morley, 1991) and experimental studies (Drost *et al.*, 1995) have revealed that the products of dipole moment and molecular hyperpolarizability ( $v\beta$ ) of thiophene-containing conjugated moieties are superior to that of benzene analogues. Based on this reason we have previously studied the compound containing thiophene unit, namely, 1-methyl-4-[*(E*)-2-(2-thienyl)ethenyl]-pyridinium 4-chlorobenzenesulfonate (Chantrapromma *et al.*, 2008). In this paper we have synthesized the title compound which was designed by the replacement of the cationic 3-hydroxy-4-methoxyphenyl ring that is present in a compound possessing second-harmonic-generation (SHG) properties, 2-[*(E*)-2-(3-hydroxy-4-methoxyphenyl)ethenyl]-1methylquinolinium, iodide monohydrate (Chantrapromma, Jindawong, Fun & Patil, 2007) by the thiophene unit. Herein we report the synthesis and crystal structure of the title compound.

The asymmetric unit of the title compound (Fig. 1) consists of the  $C_{16}H_{14}NS^+$  cation and  $I^-$  ion. The cation exists in the *E* configuration with respect to the  $C10=C11$  double bond [1.350 (3) Å] and is almost planar with the interplanar angle between the quinolinium and the thiophene ring being 11.67 (11)° and the torsion angles  $C9-C10-C11-C12 = -178.56$  (17)°. The ethenyl unit is co-planar with the thiophene ring as can be indicated by the torsion angles  $C10-C11-C12-C13 = -179.42$  (18)° and  $C10-C11-C12-S1 = 1.4$  (3)°. It is slightly deviated from the quinolinium ring with the torsion angle  $C8-C9-C10-C11 = -14.2$  (3)°. The atom S1 of the thiophene ring contributes to the  $C-H\cdots S$  intramolecular weak interaction (Fig. 1 and Table 1) forming S(5) ring motifs (Bernstein *et al.*, 1995). The bond lengths and angles are normal (Allen *et al.*, 1987) and are comparable with closely related structures (Chantrapromma *et al.*, 2006, 2008; Chantrapromma, Jindawong & Fun, 2007; Chantrapromma, Jindawong, Fun & Patil, 2007).

In the crystal packing (Fig. 2), the  $I^-$  ion is in between each pair of the two antiparallel cations and is linked with the cations through weak  $C-H\cdots I$  interactions. The crystal is stabilized by weak  $C-H\cdots S$  and  $C-H\cdots I$  interactions (Table 1). A  $\pi-\pi$  interaction was observed with the  $Cg_1\cdots Cg_2$  distance of 3.6818 (13) Å;  $Cg_1^i$  and  $Cg_2^i$  are the centroids of the S1/C12–C15 and N1/C1/C6–C9 rings, respectively [symmetry code: (i): 1 -  $x$ , 1 -  $y$ , 1 -  $z$ ]. The perpendicular distances of  $Cg_2$  onto the plane of the S1/C12–C15 ring and  $Cg_1$  onto the plane of the N1/C1/C6–C9 ring are 3.200 and 3.500 Å, respectively.

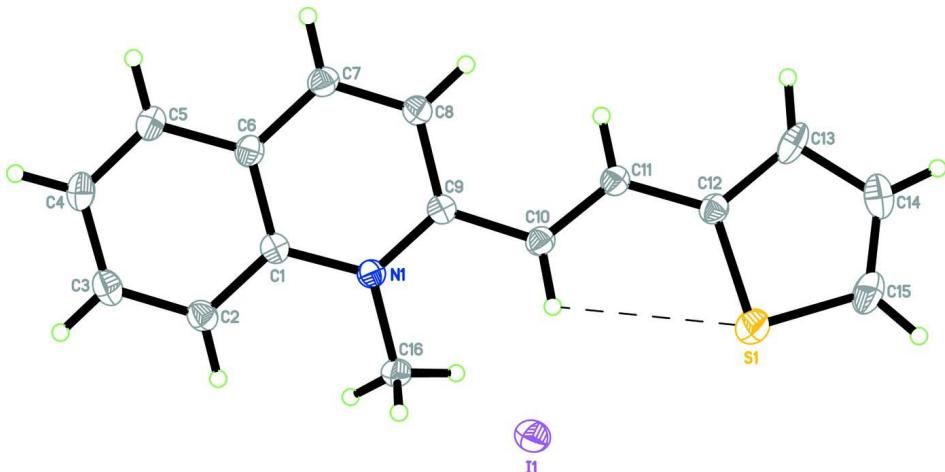

### S2. Experimental

2-(2-Thiophenestryl)-1-methylquinolinium iodide was synthesized by mixing a solution (1:1:1 molar ratio) of 1,2-dimethylquinolinium iodide (2.00 g, 7.0 mmol), 2-thiophenecarboxaldehyde (0.64 ml, 7.0 mmol) and piperidine (0.69 ml, 7.0 mmol) in hot methanol (40 ml). The resulting solution was refluxed for 5 hr under a nitrogen atmosphere. The resultant solid was filtered off and washed with diethyl ether. Brown block-shaped single crystals of the title compound

suitable for *x*-ray structure determination were obtained after recrystallization from methanol by slow evaporation of the solvent at room temperature after a few weeks.

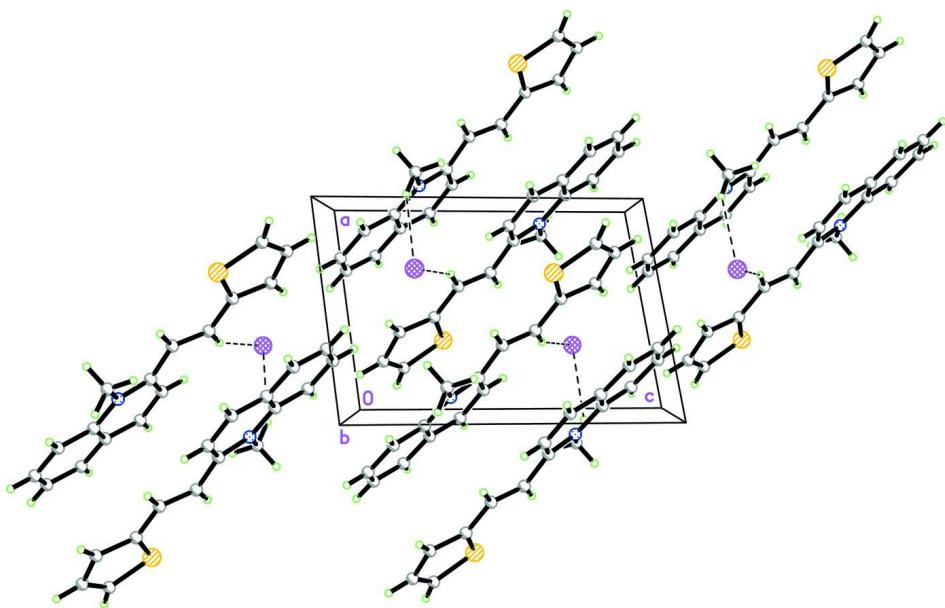

### S3. Refinement

All H atoms were placed in calculated positions ( $C—H = 0.93\text{--}0.96 \text{ \AA}$ ) and were refined as riding, with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  or  $1.5U_{\text{eq}}(\text{methyl C})$ . A rotating group model was used for the methyl group. The highest residual electron density peak is located at  $0.75 \text{ \AA}$  from atom I1 and the deepest hole is located at  $0.38 \text{ \AA}$  from atom S1.

**Figure 1**

The title compound showing 50% probability displacement ellipsoids and the atom-numbering scheme. The weak  $C—H\cdots S$  intramolecular interaction was drawn as a dashed line.

**Figure 2**

The packing diagram of the title structure, viewed approximately along the  $b$  axis. Weak  $C—H\cdots I$  interactions were drawn as dashed lines.

*Special details*

**Experimental.** The low-temperature data was collected with the Oxford Cryosystem Cobra low-temperature attachment.  
**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
