Received 10 October 2008; accepted 13 October 2008
Key indicators: single-crystal X-ray study; $T=170 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.003 \AA$; $R$ factor $=0.047 ; w R$ factor $=0.090 ;$ data-to-parameter ratio $=20.0$.

In the crystal structure of the title compound, $[\mathrm{Cu}(\mathrm{NCS})-$ $\left.\left(\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{~N}_{2}\right)\right]_{n}$, the $\mathrm{Cu}^{\mathrm{I}}$ atom is coordinated by two N atoms from two symmetry-related 4,4'-bipyridine (bipy) ligands and one N and one S atom from two symmetry-related thiocyanate ligands in a distorted tetrahedral environment. The thiocyanate ligands bridge the $\mathrm{Cu}^{1}$ atoms into a zigzag $[\mathrm{CuSCN}]_{n}$ chain running parallel to the $a$ axis. These chains are further connected through two bipy ligands that bridge the $\mathrm{Cu}^{\mathrm{I}}$ centers to generate a two-dimensional brick-like network. The pyridyl planes of the ligands exhibit a dihedral angle of 37.35 (12) ${ }^{\circ}$.

## Poly[ $\mu-4,4^{\prime}$-bipyridine- $\kappa^{2} N: N^{\prime}-\mu$-thiocyanato- $\kappa^{2} N: S$-copper(I)]

Mario Wriedt, Sina Sellmer and Christian Näther

## S1. Comment

In our ongoing investigation on the synthesis, structures and properties of new coordination polymers based on metal halides as well as pseudohalides and N -donor ligands, we have startet systematic investigation on their thermal behavior because we have demonstrated that new ligand deficient coordination polymers can be conveniently prepared by thermal decompisition of suitable ligand rich precursor compounds (Näther, Wriedt \& Jeß, 2003; Näther \& Jeß, 2006; Bhosekar et al. 2007). If the ligand rich precursor compounds contain besides the N -donor ligands paramagnetic metal atoms and small magnetically active ligands like $\mathrm{SCN}^{-}$, ligand deficient compounds with briding $\mathrm{SCN}^{-}$ligands are obtained, which show cooperative magnetic phenomena at lower temperatures (Näther \& Greve, 2003). During these investigations we have reacted copper(II)chloride and potassium thiocyanate with bipy. In this reaction the diamagnetic copper(I) title compound has been formed by accident.
The coordination properties of bipy enables a series of different coordination modes, because it can connect two different metal cations. In addition, typical $\mathrm{Cu}-\mathrm{S}-\mathrm{C}$ angles in CuSCN polymers are in the range of $100-106^{\circ}$ (Healy et al. 1984) and this should enable the construction of stairlike single or double $[\mathrm{Cu}(\mathrm{SCN})]$ chains in $1: 1$ and $2: 1$ complexes, whose Cu atoms can then be connected by linear spacer ligands into sheets (Näther \& Jeß, 2001; Näther et al. 2002; Näther, Greve \& Jeß, 2003).
The 1:1 title compound $[\mathrm{CuSCN}(\text { bipy })]_{\mathrm{n}}$, whose structure (Fig. 1) represents a two-dimensional CuSCN coordination polymer, contains single [CuSCN] ribbons (Fig. 2) as a characteristic motif. Copper(i) thiocyanato compounds with pyrazine (Goher \& Mautner, 1999), methylpyrazine (Teichert \& Sheldrick, 1999) and 1,2-bis(4-pyridyl)ethane (Wang et al. 1999) as ligand show a similar topology. Within each layer the metal ions are bridged by two $\mu_{2}\left(N, N^{\prime}\right)$-bipy ligands and two $\mu(N, S)$-thiocyanato groups. Thus, each copper(i) atom is tetrahedrally coordinated. The angels arround the copper(i) atoms range between 97.36 (9) and 115.22 (7) ${ }^{\circ}$ and the $\mathrm{Cu}-\mathrm{SCN}$ and $\mathrm{Cu}-\mathrm{NCS}$ distances amount to 2.2755 (8) and 1.966 (2) $\AA$, respectively. The $\mathrm{Cu}-\mathrm{N}_{\text {bipy }}$ distances ranges from 2.080 (2) to 2.122 (2) $\AA$ (Tab. 1). The layers can be described as formed by two types of perpendicular zigzag like chains crossing at the copper(i) centers. Chains of the first type run along the $c$-axis and have bipy as a bridging ligand, while the second type extend along the $a$ axis containing bridging thiocyanate ligands. The intralayer $\mathrm{Cu} \cdots \mathrm{Cu}$ distances are 5.7942 (2) and 11.2037 (3) $\AA \mathrm{for} \mathrm{Cu}-$ NCS- Cu and $\mathrm{Cu}-\mathrm{bipy}-\mathrm{Cu}$, respectively. The packing of the crystal structure is achieved by stacking the twodimensional layers along the $b$-axis in corrugated sheets (Fig. 3) with an interlayer stacking distance between the centroides of the sixmembered rings of 4.237 (2) $\AA$.

## S2. Experimental

$\mathrm{CuCl}_{2}$ and bipy was obtained from Alfa Aesar, KSCN and methanol was obtained from Fluka. $0.1 \mathrm{mmol}(13.4 \mathrm{mg}) \mathrm{CuCl}_{2}$, $0.2 \mathrm{mmol}(19.4 \mathrm{mg}) \mathrm{KSCN}, 0.6 \mathrm{mmol}(93.7 \mathrm{mg})$ and 1 ml of methanol were transfered in a test-tube, which was closed and heated to $120^{\circ} \mathrm{C}$ for three days. On cooling orange block-shaped single crystals of the title compound were obtained.

## S3. Refinement

All H atoms were located in difference map but were positioned with idealized geometry and were refined isotropic with $U_{\mathrm{eq}}(\mathrm{H})=1.2 U_{\mathrm{eq}}(\mathrm{C})$ of the parent atom using a riding model with $\mathrm{C}-\mathrm{H}=0.95 \AA$.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
