# 8-Iodoquinolinium triiodide tetrahydrofuran solvate

Jung-Ho Son and James D. Hoefelmeyer\*

Department of Chemistry, The University of South Dakota, 414 E. Clark Street, Vermillion, SD 57069, USA

Correspondence e-mail: jhoefelm@usd.edu

Received 4 August 2008; accepted 29 September 2008

 Key indicators: single-crystal X-ray study;  $T = 100$  K; mean  $\sigma(\text{C}-\text{C}) = 0.007$  Å;  $R$  factor = 0.026;  $wR$  factor = 0.111; data-to-parameter ratio = 19.6.

The title compound,  $\text{C}_9\text{H}_7\text{IN}^+\cdot\text{I}_3^-\cdot\text{C}_4\text{H}_8\text{O}$ , was synthesized from 8-aminoquinoline using the Sandmeyer reaction. The 8-iodoquinolinium cation is essentially planar and the triiodide ion is almost linear.  $\text{N}-\text{H}\cdots\text{O}$  hydrogen bonds, and intermolecular  $\text{I}\cdots\text{I}$  [3.7100 (5) Å] and  $\text{I}\cdots\text{H}$  interactions, between the cation, anion and solvent molecules result in the formation of sheets oriented parallel to the  $(\bar{1}03)$  plane. Between the sheets, 8-iodoquinolinium and triiodide ions are stacked alternately, with  $\text{I}\cdots\text{C}$  distances in the range  $\sim 3.8$ – $4.0$  Å.

## 8-Iodoquinolinium triiodide tetrahydrofuran solvate

J.-H. Son and J. D. Hoefelmeyer

### Comment

8-Iodoquinoline is a starting material for the synthesis of 8-substituted quinoline derivatives. The molecule 8-iodoquinoline was synthesized starting from 8-aminoquinoline using the Sandmeyer reaction (Sandmeyer, 1884), similar to the synthesis of iodobenzene (Lucas & Kennedy, 1943). During its synthesis, two 8-iodoquinolinium salt crystals, 8-iodoquinolinium chloride dihydrate (Son & Hoefelmeyer, 2008) and 8-iodoquinolinium triiodide·THF were isolated. The synthesis, characterization and crystal structure of 8-iodoquinolinium triiodide·THF are reported here.

The 8-iodoquinolinium cation is essentially planar (Fig. 1). The C9—C8—I1 angle is 121.9 (3)°, slightly larger than the ideal value of 120°. A weak intermolecular interaction is present between atom I1 of the cation and I2 of the triiodide anion; I1⋯I2(1 + x, y, 1 + z) = 3.7100 (5) Å. The geometry of triiodide is almost linear, with I2—I3 = 2.9416 (8) Å, I3—I4 = 2.9014 (8) Å and I4—I3—I2 angle is 177.445 (17)°. The shape resembles symmetric, free triiodide that typically occurs in the presence of bulky cations (Svensson & Kloo, 2003).

The 8-iodoquinolinium cation, I<sub>3</sub><sup>-</sup> and THF form an extended sheet (Fig. 2) parallel to the (T 0 3) plane through I1⋯I2, I3⋯H4 (3.15 Å) and I4⋯H5 (3.09 Å) interactions and N—H⋯O hydrogen bonds (Table 1). Between the sheets, 8-iodoquinolinium and I<sub>3</sub><sup>-</sup> ions are stacked alternately, with the I2⋯C2<sup>ii</sup>, I3⋯C8<sup>ii</sup> and I3⋯C9<sup>ii</sup> distances being 3.742 (5), 3.840 (4) and 3.838 (4) Å, respectively [symmetry code: (ii) -1/2 + x, 1/2 - y, -1/2 + z].

### Experimental

In a 500 ml beaker, a mixture of 8-aminoquinoline (10 g, 0.069 mol) and water (50 ml) was heated with stirring. While cooling the mixture in an ice bath, concentrated HCl (50 ml) was added to form a red solution. NaNO<sub>2</sub> (7.8 g, 0.113 mol) was dissolved in water (50 ml) and cooled in an ice bath separately. NaNO<sub>2</sub> solution was slowly transferred to the 8-aminoquinoline solution. Light brown precipitate formed during the addition step but eventually disappeared to form a reddish transparent solution. KI (17.9 g, 0.108 mol) was dissolved in water (25 ml) and added to the reaction mixture. Bubbles and brownish vapor evolved during addition. The solution turned to dark brown with black precipitate. The solution was refluxed with a watch glass on top of the beaker, and it became reddish brown with formation of a heavy organic layer; the black precipitate remained. After cooling and standing overnight, golden brown crystals of 8-iodoquinolinium chloride dihydrate had formed spontaneously in the solution. The mixture was neutralized upon addition of NaOH solution, which led to dissolution of the golden brown crystals and retention of the black precipitate. The liquid portion was separated from the black precipitate. 8-Iodoquinoline could be recovered from the liquid portion upon extraction with toluene. The black precipitate was dissolved in THF and crystallized by pentane vapor diffusion to obtain the crystal of 8-iodoquinolinium triiodide·THF [yield: 7.14 g (15%), m.p. 366–368 K]. <sup>1</sup>H NMR (acetone-*d*): 7.647–7.725 (dd, 1H, quin CH), 8.237–8.305 (dd, 1H, quin CH), 8.339–8.385 (dd, 1H, quin CH), 8.559–8.602 (dd, 1H, quin CH), 9.260–9.309 (dd, 1H, quin CH), 9.380–9.415 (dd, 1H, quin CH), 12.999 (br, 1H, NH). <sup>13</sup>C NMR (acetone-*d*): 91.517 (quin C8), 124.089 (quin CH), 130.558 (quin C9/10),

## supplementary materials

130.817 (quin CH), 132.183 (quin CH), 138.064 (quin C9/10), 146.463 (quin CH), 147.614 (quin CH), 149.842 (quin CH). Elemental analysis result suggests that about 75% of THF depleted during storage. Analysis calculated for  $C_{13}H_{15}I_4NO$ : C 22.03, H 2.13, N 1.98%; found: C 19.30, H 1.32, N 2.19%.

### Refinement

H atoms were positioned geometrically (N—H = 0.88 Å and C—H = 0.93 Å) and allowed to ride on the parent atoms with  $U_{iso}(H) = 1.2U_{eq}(C)$ .

*Refinement*

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: inferred from neighbouring sites
$R[F^2 > 2\sigma(F^2)] = 0.027$	H-atom parameters constrained
$wR(F^2) = 0.111$	$w = 1/[\sigma^2(F_o^2) + (0.0437P)^2 + 2.836P]$
$S = 0.98$	where $P = (F_o^2 + 2F_c^2)/3$
3363 reflections	$(\Delta/\sigma)_{\text{max}} = 0.001$
172 parameters	$\Delta\rho_{\text{max}} = 0.55 \text{ e } \text{\AA}^{-3}$
Primary atom site location: structure-invariant direct methods	$\Delta\rho_{\text{min}} = -2.63 \text{ e } \text{\AA}^{-3}$
	Extinction correction: none

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
