 Key indicators: single-crystal X-ray study;  $T = 298$  K; mean  $\sigma(\text{C}-\text{C}) = 0.008$  Å; disorder in main residue;  $R$  factor = 0.049;  $wR$  factor = 0.108; data-to-parameter ratio = 15.0.

The title compound,  $[\text{Rh}(\text{C}_{15}\text{H}_{16}\text{PS})(\text{C}_{18}\text{H}_{15}\text{P})(\text{CO})]$ , was synthesized from the reaction of the ligand *rac*- $[\text{Ph}_2\text{PCH}_2\text{CH}(\text{CH}_3)\text{SH}]$  with *trans*- $[\text{Rh}(\text{F})(\text{CO})(\text{PPh}_3)_2]$  in a 1:1 molar ratio in toluene. The Rh atom is four-coordinated in a distorted square-planar geometry with the P–S ligand  $[\text{Ph}_2\text{PCH}_2\text{CH}(\text{CH}_3)\text{S}]$  acting as a chelate and the  $\text{PPh}_3$  and disordered CO [site occupation factors of 0.61 (5) and 0.39 (5)] ligands completing the coordination.

## ***rac*-Carbonyl{1-[(diphenylphosphino)methyl]ethanethiolato}(triphenylphosphine)rhodium(I)**

**S. Hernández-Ortega and D. Morales-Morales**

### **Comment**

In recent years, attention has increasingly been paid to the coordination chemistry of polydentate ligands incorporating both thiolate and tertiary phosphine donor ligands, as their combination is likely to confer unusual structures and reactivities on their metal complexes [Dilworth, *et al.* 2000, Morales-Morales, *et al.*, 2002]. In the specific case of compounds with platinum group metals these may be suitable species for catalytic screening. Additionally, the presence of these ligands in their transition metal complexes may render interesting behaviors in solution as these ligands can be capable of full or partial deligation (hemilability), (Dilworth & Weatley, 2000, Braunstein & Naud, 2001) being able to provide important extra coordination sites for incoming substrates during a catalytic process ([Dilworth & Weatley, 2000, Braunstein & Naud, 2001). Moreover, chiral or potentially bidentate ligands have been used extensively to perform asymmetric transformations [Au-Yeung, *et al.* 2004, & Xie *et al.*, 2008], however the most commonly employed are bidentate phosphines and the use of sulfur containing ligands has been avoided owing to the well known propensity of platinum group metals to sulfur poisoning.

Thus, owing to our continuous interest in the synthesis of transition metal complexes bearing P—S hybrid ligands [Morales-Morales, *et al.*, 2002, Gómez-Benítez, *et al.*, 2007, Fierro-Arias, *et al.* 2008] we would like to report the crystal structure of the rhodium(I) complex [Rh(Ph<sub>2</sub>PCH<sub>2</sub>CH(CH<sub>3</sub>)S)(PPh<sub>3</sub>)(CO)] (I).

The rhodium atom is four-coordinated in a distorted square planar geometry with the P—S ligand [Ph<sub>2</sub>PCH<sub>2</sub>CH(CH<sub>3</sub>)S] acting as a chelate and the PPh<sub>3</sub> and CO ligands completing the coordination sphere (Fig. 1). Similar geometry has been found in a previously reported rhodium complex (Lee *et al.*, 2002). The phenyl ring on the P atoms are essentially planar, these phenyl rings are rotated around the P—C bond, forming the dihedral angles with the coordination plane P1-C34-P2-S1 (Table 1).

### **Experimental**

Synthesis of [Rh(Ph<sub>2</sub>PCH<sub>2</sub>CH(CH<sub>3</sub>)S)(PPh<sub>3</sub>)(CO)] (1). To a solution of *trans*-[Rh(F)(CO)(PPh<sub>3</sub>)<sub>2</sub>] (100 mg, 12 mmol) in toluene (25 ml) 1 equivalent of the ligand *rac*-[Ph<sub>2</sub>PCH<sub>2</sub>CH(CH<sub>3</sub>)SH] in toluene (10 ml) was added under stirring. The resulting mixture was allowed to stir overnight. After this time, the solvent was taken off under vacuum and the residue recrystallized from a double layer solvent system CH<sub>2</sub>Cl<sub>2</sub>/MeOH to afford complex 1 as a microcrystalline yellow powder. Yield 87%. <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>), (7.00–8.00 (m, Ph, 25H), 2.90–3.20 (m, CH<sub>2</sub>, 2H), 2.40–2.70 (m, CH, 1H), 1.30–1.50 (d, CH<sub>3</sub>, 3H); <sup>31</sup>P-NMR (121 MHz, CDCl<sub>3</sub>), (68.21 (dd), 59.86 (dd) 1J<sub>Rh-P</sub> = 133.4 Hz, 2J<sub>P-P</sub> = 304.2 Hz. Elem. Anal. Calculated for [C<sub>34</sub>H<sub>31</sub>OP<sub>2</sub>RhS] Calc. %: C: 62.49, H: 4.94. Found %: C: 62.50, H: 4.90. MS-FAB+ [*M*+ ] = 653 *m/z*.

### **Refinement**

All H atoms were fixed geometrically and treated as riding with C—H = 0.98 Å (methyne), 0.97 Å (methylene), 0.96 Å (methyl) and 0.93 Å (aromatic) with U<sub>iso</sub>(H) = 1.2U<sub>eq</sub>(aromatic, methylene, methine) or U<sub>iso</sub>(H) = 1.5U<sub>eq</sub>(methyl).

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
