Correspondence e-mail: bsmucker@austincollege.edu

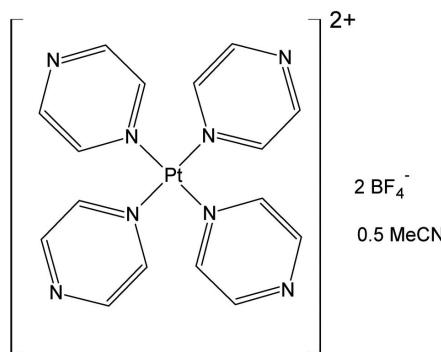

Received 1 September 2008; accepted 15 October 2008

Key indicators: single-crystal X-ray study;  $T = 296$  K; mean  $\sigma(\text{C}-\text{C}) = 0.013$  Å; disorder in solvent or counterion;  $R$  factor = 0.033;  $wR$  factor = 0.114; data-to-parameter ratio = 16.4.

The improved synthesis and characterization of tetrapyrazineplatinum(II) bis(tetrafluoroborate) acetonitrile hemisolvate,  $[\text{Pt}(\text{C}_4\text{H}_4\text{N}_2)_4](\text{BF}_4)_2 \cdot 0.5\text{CH}_3\text{CN}$ , is reported. The unit cell contains a half equivalent of an acetonitrile solvent molecule per tetrapyrazineplatinum(II) ion. The coordination geometry of the  $\text{Pt}^{II}$  ion is almost square-planar, with the Pt atom residing on an inversion center. The  $\text{BF}_4^-$  counter-anion, located at a general position, has an idealized tetrahedral geometry and an acetonitrile solvent molecule, the methyl group of which is disordered over two equal positions, sits on a twofold rotation axis.

## Tetrapyrazineplatinum(II) bis(tetrafluoroborate) acetonitrile hemisolvate

**Paul J. Derry, Xiaoping Wang and Bradley W. Smucker**

### S1. Comment

The synthesis of the nitrate salt of tetrapyrazineplatinum(II), which has use as a precursor to other platinum compounds, was recently reported in low yield (Klika *et al.*, 2007). In our pursuit of utilizing pyrazine as a bridging ligand to form compounds which add to the growing number of supramolecular metallacycles such as those by Schweiger *et al.* (2001), Willermann *et al.* (2006), and Derossi *et al.* (2007), to name but a few, we sought a more favorable yield for this tetrapyrazineplatinum(II) precursor. We settled on a synthetic method that generates a high yield of tetrapyrazineplatinum(II) tetrafluoroborate following the use of a large excess of pyrazine and nitromethane, a non-coordinating solvent which Pearson *et al.* (1960) reported as increasing the lability of a ligand bound to Pt<sup>II</sup>.

The structure of the cation of tetrapyrazineplatinum(II) tetrafluoroborate (Figure 1) has a square planar conformation. The Pt<sup>II</sup> ion resides on an inversion center with Pt1—N1 and Pt1—N2 distances of 2.026 (6) and 2.012 (5) Å, respectively. The two unique coordinated pyrazine ligands (N1 C1 C2 C3 C4 N3, N2 C5 C6 C7 C8 N4) are slightly canted relative to the (N1—Pt—N2) plane (dihedral angles between pyrazine planes and N1—Pt1—N2 plane are 84.1 (3)° and 69.3 (3)°, respectively). The canted conformation of the pyrazine ligands around the platinum atom is similar to that of pyridine in the closely-related tetrapyridine platinum(II) chloride trihydrate reported by Wei *et al.* (1989).

The tetrafluoroborate anion is positioned near three tetrapyrazineplatinum(II) cations and oriented such that every fluorine atom is between 2.1 and 2.4 Å from a hydrogen atom in the 3 or 5 position of a coordinated pyrazine. (Figure 2).

### S2. Experimental

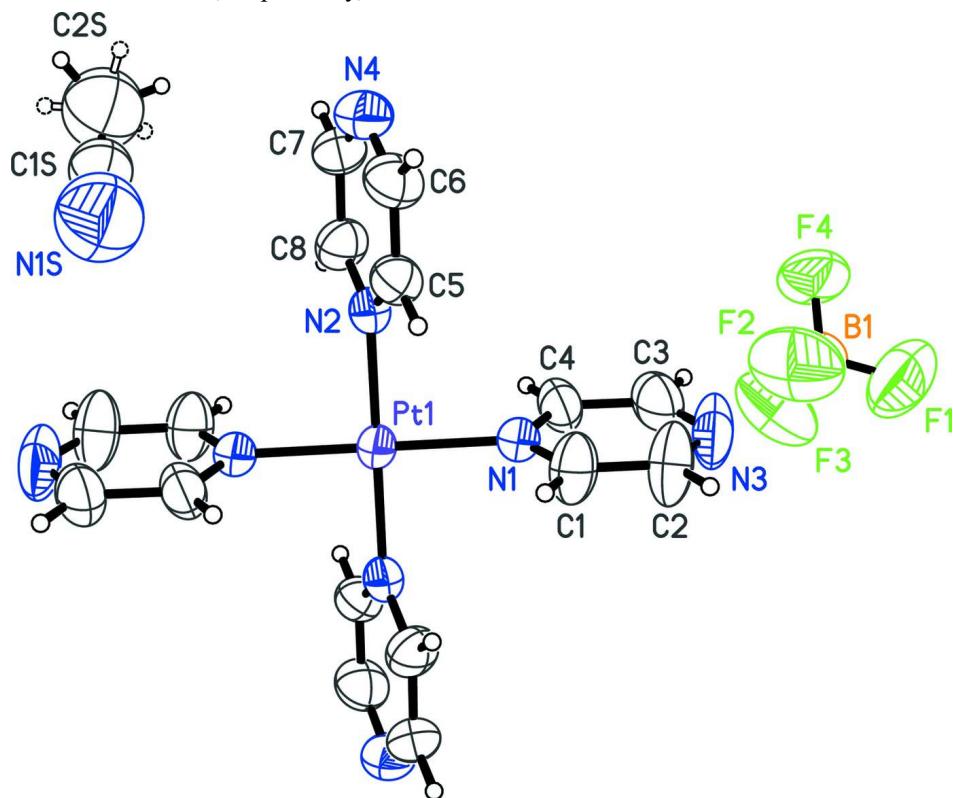

53 mg (0.099 mmol) of [Pt(NCMe)<sub>4</sub>](BF<sub>4</sub>)<sub>2</sub>, (synthesized according to Wendt *et al.* (1997)) and 344 mg (4.3 mmol) of pyrazine (Aldrich) were dissolved in 11 ml of degassed MeNO<sub>2</sub>. The schlenk flask was covered in foil and the stirring solution was moderately heated under a nitrogen environment for 18 h. 50 ml of degassed Et<sub>2</sub>O was added, the solution was cooled in an ice bath, and the resulting white solid was isolated by removal of the liquid *via* cannula and washing with 2x5mL degassed Et<sub>2</sub>O. The resulting solid was vacuum dried to give 67 mg (98% yield.) of a white solid. FT—IR (nujol, CsI plates): (cm<sup>-1</sup>) 1433(s,C—H), 1055 (b,B—F), 520 and 503 (w, Pt—N). <sup>1</sup>H NMR (d-MeNO<sub>2</sub>): 9.00 (*m*) and 8.79 (*m*). ESI-*M. S.* 602 ([Pt(C<sub>4</sub>H<sub>4</sub>N<sub>2</sub>)<sub>4</sub>](BF<sub>4</sub>)<sup>+</sup>), 258 ([Pt(C<sub>4</sub>H<sub>4</sub>N<sub>2</sub>)<sub>4</sub>]<sup>2+</sup>).

Pale yellow crystals were grown by liquid diffusion of diethylether into a nitromethane solution containing tetrapyrazineplatinum(II) tetrafluoroborate and excess pyrazine.

### S3. Refinement

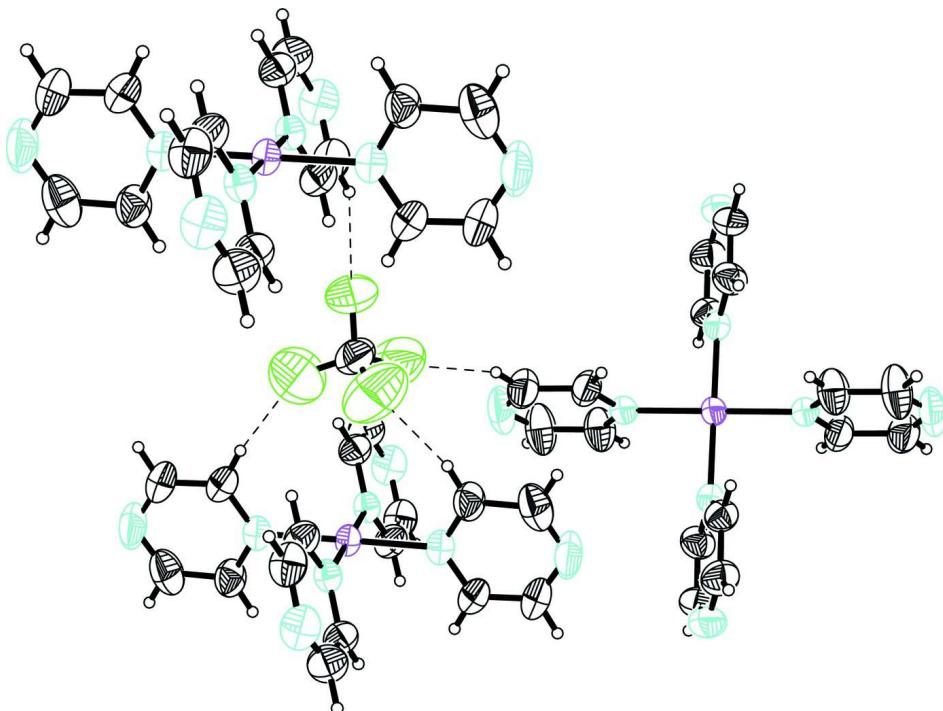

The positions of the pyrazine and methyl H atoms were refined using a riding model, in accordance with the HFIX 43 and HFIX 137 instructions of SHELXL97, with pyrazine C—H distances of 0.93 Å, methyl C—H distance of 0.96 Å, and with *U*<sub>iso</sub>(H) values of 1.2Ueq(C) for pyrazine and 1.5Ueq(C) for methyl group in the acetonitrile solvent molecule. The

acetonitrile solvate resides on a crystallographic two-fold axis with the methyl H atoms disordered in two position. Each of the methyl H atoms were refined accordingly as half occupied. The largest positive and negative peaks in the final difference map are 1.58 and -0.45 Å, respectively, from the Pt atom.

**Figure 1**

Ellipsoid plot of tetrapyrazineplatinum(II) tetrafluoroborate. Unlabelled atoms are generated via inversion through Pt1, symmetry code:  $-x, -y + 1, -z$  (50% probability displacement ellipsoids).

**Figure 2**

View of the hydrogen bonding between the tetrafluoroborate anion and the tetrapyrazineplatinum(II) cation (50% probability displacement ellipsoids).

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
