Correspondence e-mail: binboll@126.com

Received 19 August 2008; accepted 15 October 2008

Key indicators: single-crystal X-ray study;  $T = 293$  K; mean  $\sigma(\text{C}-\text{C}) = 0.022$  Å;  $R$  factor = 0.100;  $wR$  factor = 0.281; data-to-parameter ratio = 17.9.

The structure of the electrochemically crystallized title compound,  $(\text{C}_{10}\text{H}_8\text{S}_8)_3[\text{CoCl}_4]_2$ , consists of two types of bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) radical cation stacks separated by sheets of tetrahedral  $[\text{CoCl}_4]^{2-}$  anions. One of the BEDT-TTF molecules is generated by inversion. There are short  $\text{S}\cdots\text{S}$  contacts between the stacks in the  $a$  direction and short  $\text{C}-\text{H}\cdots\text{Cl}$  contacts between the radical cations and the anions.

## Bis(ethylenedithio)tetrathiafulvalenium-tetrachloridocobaltate(II) (3/2)

F. Zhao, P. Li, X. Zhu and L. Dong

### Comment

There is a large variety of quasi-two-dimensional organic conductors based on the radical cation salts of bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) which also is abbreviated to ET. They show a wealth of structural modifications, but the conducting properties of the radical salts are essentially determined by the packing patterns of their BEDT-TTF layers (Shibaeva & Yagubskii, 2004). So, according to packing patterns of the BEDT-TTF layers in the various crystal structure, it is customary classified as  $\alpha$ ,  $\beta$ ,  $\delta$ ,  $\chi$  and so on. (Mori, 1998; Mori, 1999; Mori *et al.*, 1999)

In the title structure, (I), the unit cell contains three ET donors and two anions. Since one BEDT-TTF molecule (ETA) and  $[\text{CoCl}_4]^{2-}$  anion are on general positions, and the other BEDT-TTF molecule (ETB) is positioned on an inversion center, the crystallographically independent molecules are 1.5 ET molecules and one  $[\text{CoCl}_4]^{2-}$  anion (Fig. 1). The  $[\text{CoCl}_4]^{2-}$  anion shows a slightly distorted tetrahedral configuration (Table 1). The two independent ET molecules have different molecular configuration. In the ETA, the terminal ethylene C2 and C9 atoms extend from the molecular plane with deviations of  $-0.499$  (16) Å and  $-0.579$  (18) Å, but C1 and C10 atoms [with deviations of  $0.169$  (17) Å and  $0.057$  (19) Å] almost share the same plane with the rest of the molecule. ETA shows a boat conformation in which C2 and C9 are on the both sides of the molecular plane. Otherwise, ETB shows a chair conformation in which C11 and C12 deviate from the molecular plane by  $0.658$  (18) Å and  $0.02$  (2) Å respectively and the inversion center positioned on the middle of the C15—C15A bond. The dihedral angle between the molecular planes of ETA and ETB is  $16.88$  (16)° and their molecular planes make angles of  $43.93$  (10)° and  $27.10$  (13)° with  $[010]$  directions respectively.

ETA and ETB form stack A and stack B along the  $b$  axis in a face to face manner with different intra-stack packing modes. In the stack A, ETA molecules are dimerized and the intra-stack packing mode alternates between the ROB [ring over bond, ET molecules stack on top of each other with a relative displacement between stacking molecules along their long in-plane axes] and ROA [ring over atom, ET molecules stack on above or below with a large displacement between stacking molecules along their short in-plane axes] modes, as defined by Williams *et al.* (1984). The mean interplanar distance in the dimerized ET molecules is  $3.606$  Å and between the dimerized is  $3.082$  Å. There are three kinds of intra-dimer S...S short distances within each dimer shorter than the combined van der Waals radii of two sulfur atoms ( $3.60$  Å), but there are no obvious inter-dimer S...S short contacts between the dimers. Stack B contains only ETB molecules overlapped with ROB mode, and there are no intrastack S...S short contacts. The mean interplanar distance in stack B is  $4.392$  Å.

Stack A and Stack B form layer A and layer B in the  $ab$  plane respectively and these layers are interleaved by the inorganic anions. In layer A, one ET molecule has four pairs of inter-stack S...S short contacts between the stacks in the  $a$ -direction [ $\text{S1}\cdots\text{S2} = 3.518$  (6) Å,  $\text{S1}\cdots\text{S4} = 3.562$  (6) Å,  $\text{S7}\cdots\text{S8} = 3.549$  (6) Å] as shown in Fig. 2. Combined with intra-stack S...S short contacts within Stack A, it is suggested that the possibility of a quasi-two-dimensional interaction in the  $ab$ -plane. In contrast to the layer A, there are no S...S distance are shorter than the sum of van der Waals radii of two sulfur atoms in the layer B, which indicates the absence of any intermolecular interaction in the layer B.

## supplementary materials

---

Between layer A and layer B, there are layers of  $[\text{CoCl}_4]^{2-}$  anions, which engage in ionic donor-anion interactions. The anions sandwich the layers A and layers B along the  $c$  axis. The  $[\text{CoCl}_4]^{2-}$  anions are situated in the so called 'anion cavity', which is bonded by the terminal ethylene groups of the ET cations. Short C—H $\cdots$ Cl interactions (Table 2) probably stabilize the crystal structure.

Among the molecular conductors based on the ET, there are three major determinant of packing of a crystal: (1) the ET network packing motif; (2) the anion layer motif; and (3) the interatomic environment at the interface of the donor and anion layers. For the larger size of the ET and fractional charge on it, the coulomb interaction between the ET cations and anions is inferior to the  $\pi$ - $\pi$  interaction. In the title crystal, the ET molecules form poly-ET cations by the  $\pi$ - $\pi$  interaction and  $[\text{CoCl}_4]^{2-}$  anions fill the cavity formed by the ethylene groups of the surrounding ET molecules to balance charge. Hence, the 'anion cavity' is mainly determined by the ET packing motif where the 'anion cavity' is a trigonal channel along the [100] directions. If the size of anion is not enough to fill the anion cavity, the solvent molecules will be crystallized in the crystal to stabilize the structure, such as TCE(1,1,2-trichloroethane) molecules in the crystal  $\alpha$ - $\text{ET}_3(\text{CoCl}_4)(\text{TCE})$  (Mori *et al.*, 2002). In the crystal  $\alpha$ - $\text{ET}_3(\text{CoCl}_4)(\text{TCE})$ , the oxidation on ET molecules is lower than that in the title compound, where only one  $[\text{CoCl}_4]^{2-}$  anion is needed to balance charge, so the TCE solvent molecules are filled in the 'anion cavity' together. At the same time, if some of the anions are replaced by the other anion with same geometry, size and charge, the crystal structure will be an isomorphic structure, for example,  $\beta$ - $(\text{ET})_3(\text{CoCl}_4)_{1.34}(\text{GaCl}_4)_{0.66}$ ,  $\alpha$ - $\text{ET}_3(\text{CoCl}_4)_{0.38}(\text{CoCl}_4)_{0.62}(\text{TCE})$  (Mori *et al.*, 2002). On the other hand, the oxidation on ET molecules and the interaction between the anions and the ethylene groups of the ET will significant affect the packing motif of the ET cations, so the ET packing motif of the title crystal belongs to  $\beta'$  and  $\text{ET}_3(\text{CoCl}_4)(\text{TCE})$  belongs to  $\alpha$ . But the 'anion cavity' formed by the ET cations as above two packing motif are nearly same.

### Experimental

BEDT-TTF was synthesized following the method of Varma *et al.* (1987) and recrystallized from  $\text{CHCl}_3$ .  $\text{K}_2\text{CoCl}_4 \cdot 6\text{H}_2\text{O}$  was synthesized by metathesis of  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  and  $\text{KCl}$  in a molar ratio of 1:2 in water and recrystallized before use. All solvent were distilled before use.

Electrochemical crystal growth was carried out in conventional H-shaped cells with Pt electrodes in a constant temperature of 295 (2) K at a current of 0.2  $\mu\text{A}$ . Each cell contained 7 mg of BEDT-TTF and 99.3 mg of  $\text{K}_2\text{CoCl}_4 \cdot 6\text{H}_2\text{O}$  together with 40 mg of 18-crown-6 in 35 mL of TCE(1,1,2-trichloroethane) under an inert atmosphere ( $\text{N}_2$ ). Black needles of (I) were obtained after three months.

### Refinement

The electrocrystallization process is a 'self-assembly' process which is difficult to control. The tendency to grow as bundles of fine needles has hampered our efforts to get a better crystal. The low quality of the crystal was the reason for low bond precision, but the obtained structure information of the title compound is meaningful.

The H atoms were geometrically placed (C—H = 0.97 $\text{\AA}$ ) and refined as riding with  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ .

## Figures

289 parameters	$\Delta\rho_{\max} = 0.91 \text{ e } \text{\AA}^{-3}$
8 restraints	$\Delta\rho_{\min} = -1.06 \text{ e } \text{\AA}^{-3}$
Primary atom site location: structure-invariant direct methods	Extinction correction: none

## Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
