Received 12 December 2008; accepted 17 December 2008

 Key indicators: single-crystal X-ray study; $T = 298$ K; mean $\sigma(\text{C}-\text{C}) = 0.004$ Å; R factor = 0.039; wR factor = 0.106; data-to-parameter ratio = 16.1.

The title compound, $(\text{C}_5\text{H}_6\text{N}_3\text{O}_2)_2[\text{Cr}_2\text{O}_7]$, consists of 2-amino-3-nitropyridinium cations and discrete dichromate anions linked together by $\text{N}-\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonds, forming thick layers parallel to (101). Layer cohesion is ensured by $\text{N}-\text{H}\cdots\text{O}$ hydrogen bonding in addition to electrostatic and van der Waals interactions, forming a three-dimensional framework. The dichromate anion is located on a twofold axis that passes through its bridging O atom.

Bis(2-amino-3-nitropyridinium) dichromate(VI)

S. Akriche and M. Rzaigui

Comment

A new engineering strategy using organic-inorganic hybrid materials have appeared over the past years. The challenge was to combine the advantages of organic crystals and those of the inorganic materials. As a part of our study of crystal packing in amino-nitro "push-pull" system, a new organic-inorganic salt, bis (2-amino-3-nitropyridinium) dichromate (I) have been synthesized.

The dichromate anion has a binary internal symmetry since its bridging oxygen atom is located on a twofold axis, and so is built by only one independent (CrO_4) group. This later with one independent (2-NH₂-3-NO₂C₅H₃NH)⁺ cation constitute the asymmetric unit of (I) (Fig. 1).

As expected, the main geometrical features of anion agree with those previously observed for this group in other compounds (Sieroń, 2007; Khadhrani *et al.*, 2006). The bond lengths and the angles within the cation are comparable with those observed for 2-amino-3-nitropyridinium dihydrogenphosphate (Akriche *et al.*, 2000), 2-amino-3-nitropyridinium hydrogensulfate (Le Fur *et al.*, 1998) and 2-amino-3-nitropyridinium chloride (Nicoud *et al.*, 1997).

The dichromate and organic entities manifest different interactions (electrostatic, H-bonds, Van Der Waals) to keep up the three-dimensional network cohesion (Fig. 2). The main links are from the N—H \cdots O bonds (Table 1) with H \cdots O bond lengths falling in the range from 1.87–2.59 Å.

Long C—H \cdots O contacts occur between cations and cation-anion moieties with C \cdots O bond lengths ranging from 3.494 (4)–3.232 (4) Å (Desiraju, 1989; Desiraju, 1995).

It's worth noticing the intracation contact N2—H2B \cdots O6 (see Table 1 for symmetry code) which is always present in nitroaniline in which nitro and amino groups are *ortho* to one another, as clearly shown in a study of hydrogen patterns of nitroaniline derivatives (Panunto *et al.*, 1987). This situation precludes the rotation of the nitro group with respect to pyridinium ring. The angle between the planes of the NO₂ group and the heterocycle is 7.98° for cation, indicating a coplanar geometry.

Experimental

0.004 mol of 2-amino-3-nitropyridine was dissolved in 20 ml of pure acetic acid. 5 ml solution containing 0.004 mol of CrO₃ was added drop by drop under stirring at 333 K. The obtained solution is slowly evaporated at the ambient temperature. After some days, Brown single crystals of the title compound are formed in the reactionnel middle.

Figures

Fig. 1. An ORTEP view of (I) with the atom-labelling scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are represented as small spheres of arbitrary radii. Hydrogen bonds are represented as dashed lines. [Symmetry code: (i) $-x+1, y, -z+1/2$]

Extinction correction: none

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
