Key indicators: single-crystal X-ray study; $T = 298$ K; mean $\sigma(\text{N}-\text{C}) = 0.02$ Å; R factor = 0.059; wR factor = 0.135; data-to-parameter ratio = 23.2.

The Hg atom in the crystal structure of the title compound, $(\text{CH}_6\text{N}_3)_2[\text{HgI}_4]$, is tetrahedrally coordinated by four I atoms. The $[\text{HgI}_4]^{2-}$ ions are interconnected to the $[\text{C}(\text{NH}_2)_3]^+$ ions by $\text{N}-\text{H}\cdots\text{I}$ hydrogen bonds, forming a three-dimensional network. The four different observed Hg—I distances [2.760 (2), 2.7762 (15), 2.8098 (14) and 2.833 (2) Å] are consistent with four different ^{127}I NQR frequencies observed, showing the existence of four unique I atoms in the tetraiodidomercurate unit.

Related literature

For synthetic methods, see: Furukawa *et al.* (2005); For the ability of the guanidinium ion to make hydrogen bonds and its unique planar shape, see: Terao *et al.* (2000). Hg—halogen bonds are sensitive to intermolecular interactions such as hydrogen bonding (Ishihara *et al.*, 2002), as evidenced by the halogen NQR of Hg compounds in which the resonance frequencies are widely spread (Furukawa *et al.*, 2005). For background to this study, see: Terao *et al.* (2009).

Bis(guanidinium) tetraiodidomercurate(II)

H. Terao, T. M. Gesing, H. Ishihara, Y. Furukawa and B. T. Gowda

Comment

The ability of guanidium ion, $[\text{C}(\text{NH}_2)_3]^+$ in making hydrogen bonds and its unique planar shape has been recognized (Terao *et al.*, 2000). Further, the guanidium ions tend to undergo reorientation motions about their (pseudo) C_3 axes in the crystals. Due to the soft nature, Hg atoms are amenable to polarization and thus the Hg-halogen bonds are sensitive to the intermolecular interactions such as hydrogen bonding (Ishihara *et al.*, 2002). This was evident in the halogen NQR of the Hg compounds in which the resonance frequencies are widely spread (Furukawa *et al.*, 2005). Thus the study of the structure and bonding of this class of compounds is interesting. As a part of our investigations in this direction (Terao *et al.*, 2009), we report herein the crystal structure of Guanidinium tetraiodidomercurate(II) (I). In the structure, the mercury atom is tetrahedrally coordinated by four iodine atoms and the resulting HgI_4 tetrahedra are interconnected to the $[\text{C}(\text{NH}_2)_3]^+$ ions by iodine-hydrogen bonds forming a three-dimensional network (Fig. 1). Four different Hg—I distances were observed which are consistent with four different I-127 NQR frequencies observed (Furukawa *et al.*, 2005), establishing the existence of four inequivalent I atoms in the tetraiodidomercurate unit. The packing diagram of the crystal structure, as viewed in the direction of c axis is shown in Fig. 3.

Experimental

Guanidinium tetraiodidomercurate(II) was prepared by slow concentration of methanolic solution containing mercuric iodide (0.01 mol, 4.54 g) and guanidium iodide (0.024 mol, 4.48 g) in slightly more than 1:2 molar ratio. The purity of the compound was checked by elemental analysis and characterized by its NMR and NQR spectra (Furukawa *et al.*, 2005). The single crystals used in X-ray diffraction studies were grown in methanolic solution by a slow evaporation at room temperature.

Refinement

The N—H distances were restrained to 0.87–0.88 Å and the coordinates of the H atoms were refined with isotropic displacement parameters set to 1.2 times of the U_{eq} of the parent atom.

Figures

Fig. 1. Molecular structure of (I), showing the atom labeling scheme. The displacement ellipsoids are drawn at the 50% probability level. The H atoms are represented as small spheres of arbitrary radii.

Fig. 2. Two distinct guanidinium ions in the crystal structure of (I) along with the numbering of the atoms.

Fig. 3. Packing diagram of (I) as viewed in the direction of *c* axis.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
