Key indicators: single-crystal X-ray study;  $T = 150$  K; mean  $\sigma(\text{P}-\text{O}) = 0.001$  Å;  $R$  factor = 0.022;  $wR$  factor = 0.025; data-to-parameter ratio = 16.2.

The title compound, potassium nickel(II) digallium tris-(phosphate) dihydrate,  $K[\text{NiGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$ , was synthesized hydrothermally. The structure is constructed from distorted *trans*- $\text{NiO}_4(\text{H}_2\text{O})_2$  octahedra linked through vertices and edges to  $\text{GaO}_5$  trigonal bipyramids and  $\text{PO}_4$  tetrahedra, forming a three-dimensional framework of formula  $[\text{NiGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]^-$ . The K, Ni and one P atom lie on special positions (Wyckoff position 4e, site symmetry 2). There are two sets of channels within the framework, one running parallel to the  $[10\bar{1}]$  direction and the other parallel to  $[001]$ . These intersect, forming a three-dimensional pore network in which the water molecules coordinated to the Ni atoms and the  $\text{K}^+$  ions required to charge balance the framework reside. The  $\text{K}^+$  ions lie in a highly distorted environment surrounded by ten O atoms, six of which are closer than 3.1 Å. The coordinated water molecules are within hydrogen-bonding distance to O atoms of bridging Ga—O—P groups.

## Potassium nickel(II) gallium phosphate hydrate, $\text{K}[\text{NiGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$

A. M. Chippindale, A. V. Sharma and S. J. Hibble

### Comment

Although the majority of heterometal substituted gallophosphates,  $\text{MeGaPOs}$ , contain  $\text{MO}_4$  ( $M = \text{Me}$  or  $\text{Ga}$ ) and  $\text{PO}_4$  units (Baerlocher *et al.*, 2001), some are known in which the metal atoms have non-tetrahedral geometries. For example, NGP-1 (Lin & Wang, 2005), the only organically templated  $\text{NiGaPO}$  reported to date, contains  $\text{Ni}$  and  $\text{Ga}$  disordered over the same octahedral metal sites, together with  $\text{GaO}_5$  and  $\text{PO}_4$  units.  $\text{K}[\text{NiGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$  is assembled from the same polyhedra as NGP-1 and is isostructural with a number of ammonium transition-metal gallophosphates,  $\text{NH}_4[\text{MeGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$  ( $\text{Me} = \text{Mn}$  (Chippindale *et al.*, 1998),  $\text{Fe}$ ,  $\text{Ni}$  (Bieniok *et al.*, 2008),  $\text{Co}$  (Chippindale *et al.*, 1996)) and has an aluminium analogue,  $\text{K}[\text{NiAl}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$  (Meyer & Haushalter, 1994). The same structure type occurs in  $\text{Cs}[\text{Fe}_3(\text{PO}_4)_3(\text{H}_2\text{O})_2]$  (Lii & Huang, 1995) and  $\text{NH}_4[\text{CoAl}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$  (Panz *et al.*, 1998) and is related to that of  $(\text{NH}_4)_3\text{Ga}_2(\text{PO}_4)_3$  (Lesage *et al.*, 2004).

The two phosphorus atoms have tetrahedral geometry ( $\text{P1}$ , point symmetry  $\text{C}_{2v}$ ;  $\text{P2}$ , 1). Unlike in NGP-1, the metal atoms are located in two distinct sites;  $\text{Ga1}$  in a  $\text{GaO}_5$  trigonal bipyramid (1) and  $\text{Ni1}$  in a  $\text{NiO}_4(\text{H}_2\text{O})_2$  distorted octahedron ( $\text{C}_{2v}$ ), in which the terminal water molecules,  $\text{H}_2\text{O}4$ , lie *trans* to each other (Fig. 1). Two of the other oxygen atoms in the  $\text{NiO}_6$  unit,  $\text{O2}$  and  $\text{O2}^i$ , are two coordinate whilst  $\text{O3}$  and  $\text{O3}^i$  are three coordinate. As expected, the  $\text{M—O3}$  ( $M = \text{Ni}$ ,  $\text{Ga}$ ) and  $\text{P1—O3}$  bond lengths are the longest  $\text{M—O}$  and  $\text{P—O}$  bond lengths observed in the structure. Bond-valence sums (Brese & O'Keeffe, 1991) for  $\text{P1}$ ,  $\text{P2}$ ,  $\text{Ga1}$  and  $\text{Ni1}$  are 4.80, 4.81, 3.22 and 1.93, respectively, which together with the yellow colour of the crystals, confirm the presence of  $\text{Ni}^{2+}$  in the structure.

The  $\text{GaO}_5$ ,  $\text{NiO}_6$  and  $\text{PO}_4$  units link together through edge- and vertex-sharing arrangements to give a three-dimensional framework of composition  $[\text{NiGa}_2(\text{PO}_4)_3(\text{H}_2\text{O})_2]$ . A set of approximately circular channels, running parallel to the  $[10\bar{1}]$  direction, contain the water molecules and potassium ions (Fig. 2). A second set of channels, elliptical in shape, run parallel to the  $c$  axis (Fig. 3) and intersect with the first set to generate a three-dimensional pore network.

The potassium atom lies in a very distorted coordination environment with six near oxygen atoms ( $\text{K1}\cdots\text{O}$  in range 2.865 (1) to 3.072 (1) Å) with two additional O atoms at 3.397 (1) and two at 3.456 (1) Å.  $\text{H}_2\text{O}4$  is also involved in hydrogen bonding to  $\text{Ga—O—P}$  bridging oxygen atoms.

### Experimental

The title compound was prepared hydrothermally from a gel of composition  $\text{Ga}_2\text{O}_3$ : $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ : $10\text{H}_3\text{PO}_4$ : $156\text{H}_2\text{O}$ : $0.1\text{Si}(\text{OEt})_4$ : $5\text{KH}_2\text{PO}_4$  which was heated at 433 K for 7 d in a Teflon-lined stainless steel autoclave. The solid product was collected by filtration, washed with deionized water and dried in air. The product consisted of large yellow faceted blocks of the title compound, which could be easily separated from unidentified white powder.

## Refinement

Prior to refinement, reflections with  $I < 3\sigma(I)$  were omitted. The H atoms of the water molecule, H<sub>2</sub>O<sub>4</sub>, were located in a difference Fourier map. Their fractional coordinates were refined subject to bond length and angle restraints [O–H = 0.85 (1) Å, H–O–H = 109 (5) °] with isotropic displacement parameters fixed at 0.05 Å<sup>2</sup>.

## Figures

Fig. 1. Local coordination of the title compound with displacement ellipsoids drawn at the 50% probability level. H atoms are shown as spheres of arbitrary radius. [Symmetry codes: (i)  $-x, y, -z + 1/2$ ; (ii)  $x, -y, z + 1/2$ ; (iii)  $-x, -y, -z$ ; (iv)  $-x + 1/2, y + 1/2, -z + 1/2$ ; (v)  $-x + 1/2, -y + 1/2, -z$ ; (viii)  $x - 1/2, 1/2 - y, 1/2 + z$ ; (ix)  $-x + 1/2, y + 1/2, z$ ].

Fig. 2. View of the main channels running parallel to the  $[1\ 0\ T]$  direction shown as (a) ball and stick and (b) polyhedral representation. The cross pore distance  $O1 \cdots O5^x$  is 7.251 (1) Å. The colour of each polyhedron corresponds to the colour of the central atom as defined in Fig. 1. [Symmetry codes: (x)  $1/2 - x, 1/2 - y, -z$ ]

Fig. 3. View along the  $c$  axis as (a) ball and stick and (b) polyhedral representation showing the elliptical channels bounded by eight membered rings. The shortest cross channel distances are 4.092 (2) and 4.360 (1) Å for  $O2 \cdots O2^{xi}$  and  $O2 \cdots O6^{ix}$  respectively. These channels intersect with the main channels shown in Fig. 2 to form a 3-D pore network. [Symmetry codes: (ix)  $-x + 1/2, y + 1/2, z$ ; (xi)  $-x, 1 - y, z$ ].
