Received 15 May 2009; accepted 19 May 2009

Key indicators: single-crystal X-ray study; $T = 296\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.004\text{ \AA}$; R factor = 0.030; wR factor = 0.070; data-to-parameter ratio = 11.1.

Cocrystallization of 2-aminobenzothiazole with benzene-1,2,4-tricarboxylic acid in a mixed solvent affords the title ternary cocrystal, $\text{C}_7\text{H}_7\text{N}_2\text{S}^+\cdot\text{C}_9\text{H}_5\text{O}_6^- \cdot \text{H}_2\text{O}$, in which one of the carboxyl groups of the benzenetricarboxylic acid is deprotonated and the heterocyclic N atom of the 2-aminobenzothiazole is protonated. In the crystal, intermolecular $\text{N}-\text{H}\cdots\text{O}$ and $\text{O}-\text{H}\cdots\text{O}$ hydrogen-bonding interactions stabilize the packing.

2-Aminobenzothiazolium 2,4-dicarboxybenzoate monohydrate

Na Zhang, Kai-Sheng Liu and Xiao-Jun Zhao

S1. Comment

Benzothiazole and its derivatives are extensively used in the field of crystal engineering owing to their beautiful structure and potential applications as electroluminescent devices (Batista *et al.*, 2007; Leng *et al.*, 2001, Chen *et al.*, 2008), fluorescent probes for DNA (Kovalska *et al.*, 2006), and corrosion inhibitors (Marconato *et al.*, 1998).

As one of the typical benzothiazole derivatives, 2-aminobenzothiazole (Abt) has been becoming a promising candidate for both the metal complexes and organic cocrystals, because they have rigid heterocyclic backbone and functional amino group. Consequently, various Abt-based metal complexes with diverse coligands have been considerably investigated (Bati *et al.*, 2005; Sieroń *et al.*, 1999; Usman *et al.*, 2003). In contrast, the Abt-based cocrystals are limited documented (Lynch *et al.*, 1998; Lynch *et al.*, 1999). Thus, as a continuation of acid–base crystalline adducts, in the present paper, we choose Abt and aromatic 1, 2, 4-benzenetricarboxylic acid (H_3btc) as building blocks to cocrystallize. As a result, an intermolecular proton–transfer adduct, (I), was obtained, which exhibits a two-dimensional hydrogen–bonded network.

As shown in Fig. 1, the asymmetric unit of (I) comprises one HAbt cation, a monodeprotonated H_2btc anion and one water molecule. The exocyclic amino group of HAbt is roughly coplanar with the benzothiazole ring. In contrast, the deprotonated carboxy group of H_2btc makes dihedral angle of 86.103 (1) $^\circ$, and the other carboxylic groups form dihedral angles of 8.231 (1) and 1.962 (2) $^\circ$ with the benzene ring of H_2btc , respectively. The benzothiazole and the benzene rings of H_2btc exhibits a dihedral angle of 7.083 (2) $^\circ$. In the asymmetric unit, an intermolecular N2–H2B ··· O5 hydrogen–bonding interaction (Table 1) was observed to stabilize the adduct.

Two H_2btc anions from the adjacent units are held together by intermolecular O6–H6 ··· O2 interactions (Table 1) to form an infinite one-dimensional ribbon along the crystallographic *c*-axis (Fig. 2), in which lattice water molecules were entrapped by O4–H4 ··· O7 hydrogen–bonding interaction between the carboxylic group of H_2btc and water molecule..

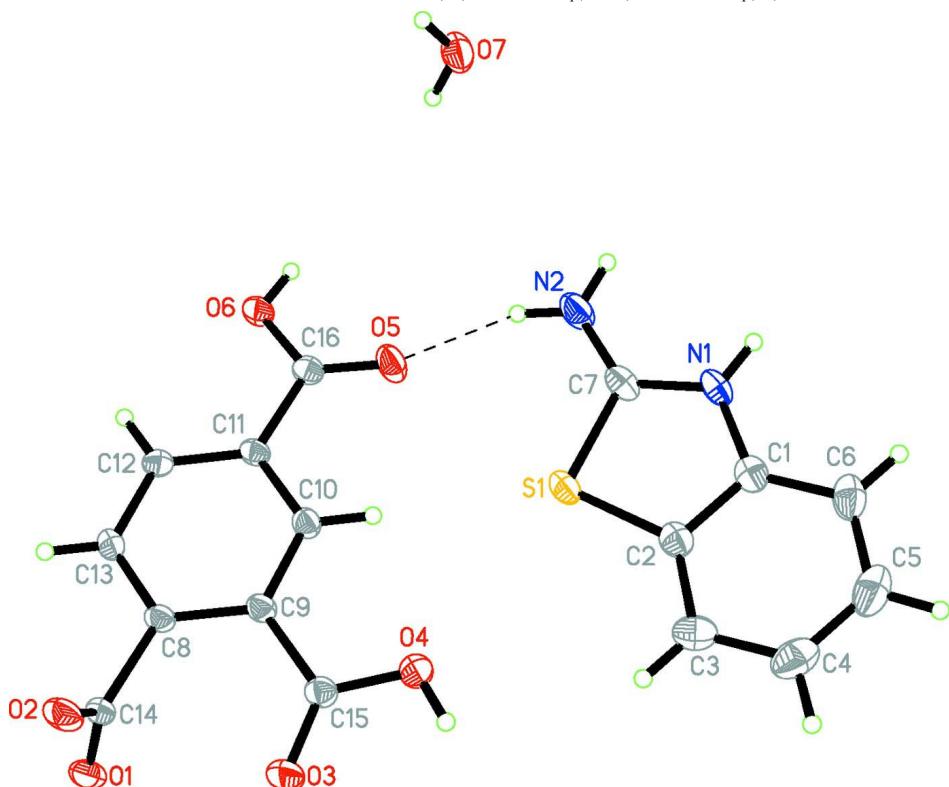

Furthermore, the neighboring 1-D ribbons are head-to-tail connected together by four fold O4–H4 ··· O7, N1–H1 ··· O1, N2–H2A ··· O3, O7–H7A ··· O1 and O7–H7B ··· O2 hydrogen-bonding to form a separate two-dimensional supramolecular sheet without any weak π ··· π interactions between neighboring sheets (Fig. 3). Thus, it can be concluded that the extensive hydrogen–bonding interactions play essentially roles for the extension of (I).

S2. Experimental

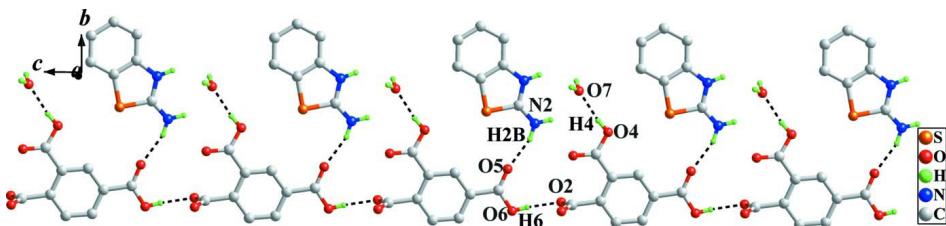

2-Aminobenzothiazole (0.1 mmol, 15.0 mg) and 1, 2, 4-benzenetricarboxylic acid (0.1 mmol, 21.0 mg) were mixed in a CH_3OH/H_2O solution (v: v = 1:1, 10 ml) and stirred constantly for about 30 min. The resulting mixture was filtered. Colorless block crystals suitable for *X*-ray diffraction were collected by slow evaporation of the filtrate within one week. Yield: 56%. Anal. Calcd for $C_{16}H_{14}N_2O_7S$: C, 50.79; H, 3.73; N, 7.40%. Found: C, 50.66; H, 3.52; N, 7.28%.

S3. Refinement

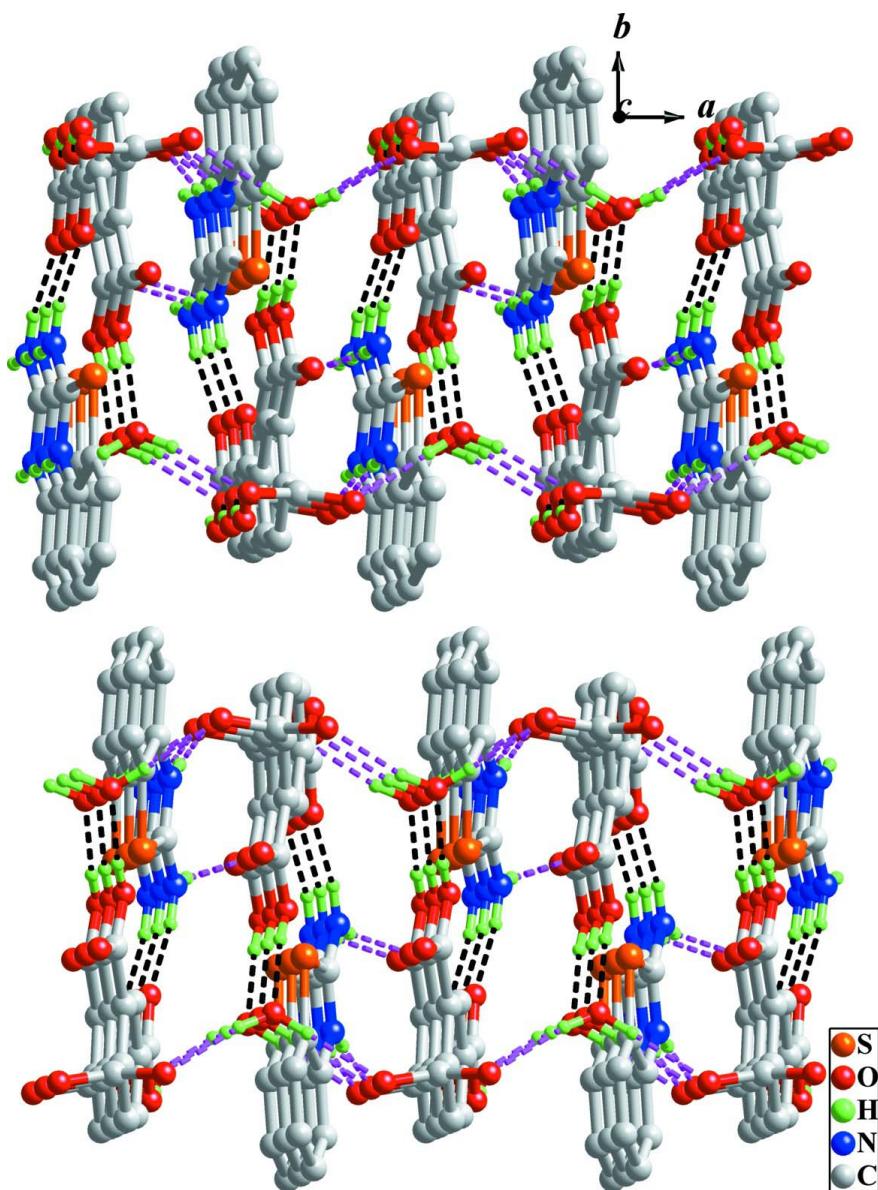

H atoms were located in difference maps, but were subsequently placed in calculated positions and treated as riding, with C – H = 0.93, O – H = 0.85, and N – H = 0.86 Å and $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C}, \text{N})$ or $1.5 U_{\text{eq}}(\text{O})$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
