Received 23 May 2009; accepted 25 May 2009

Key indicators: single-crystal X-ray study; $T = 296$ K; mean $\sigma(\text{C}-\text{C}) = 0.003$ Å; R factor = 0.039; wR factor = 0.112; data-to-parameter ratio = 19.5.

In the title compound, $\text{C}_8\text{H}_9\text{NS}$, the dihedral angle between the aromatic ring and the thioamide fragment is 36.0 (2)°. There are π -stacking interactions between coplanar aryl fragments, with a centroid-centroid separation of 3.658 (2) Å. In addition, there are intermolecular hydrogen bonds between the amino group and the S atoms.

3-Methylthiobenzamide

Mahmood-ul-Hassan Khan, Shahid Hameed, Tashfeen Akhtar and Jason D. Masuda

S1. Comment

Thioamides are not only important intermediates in the synthesis of heterocyclic compounds but they also possess enormous biological activities as reported in our previous articles (Khan *et al.*, 2009a). In the present article, we report the crystal structure of 3-methylthiobenzamide, synthesized as a continuation of our previous work on the synthesis and biological screenings of five membered heterocycles (Akhtar *et al.*, 2006, 2007, 2008; Serwar *et al.*, 2009).

There are two distinct hydrogen bonding interactions between the nitrogen and sulfur atoms. The first arranges the dimer with N \cdots S distances of 3.422 (3) Å and the second links two thioamide dimers through another N \cdots S interaction on the order of 3.455 (2) Å. These N—H \cdots S hydrogen bonding interactions are similar to those seen in *p*-trifluoromethylbenzothioamide where the corresponding interactions are between 3.3735 Å and 3.5133 Å (Jian *et al.*, 2006), in 4-chlorobenzothioamide where the N \cdots S distances are 3.3769 (15) Å and 3.4527 (15) Å (Khan *et al.*, 2009a) and in 4-bromobenzothioamide where the N \cdots S distances are between 3.500 (2) Å and 3.605 (3) Å (Khan *et al.*, 2009b).

S2. Experimental

The title compound was synthesized from 3-methylbenzonitrile according to a reported procedure (Khan *et al.*, 2009a). The recrystallization of the product from chloroform afforded crystals suitable for X-ray analysis.

S3. Refinement

The hydrogen atoms were placed in geometrically idealized positions with C—H distances of 0.93 Å (aromatic C—H), 0.96 Å (methyl) and 0.86 Å (amide N—H) and constrained to ride on the parent atom with $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ for aromatic and amide protons or $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{C}_{\text{methyl}})$.

 $\Delta\rho_{\min} = -0.29 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
