Received 13 July 2009; accepted 17 September 2009
Key indicators: single-crystal X-ray study; $T=110 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.041 ; w R$ factor $=0.118 ;$ data-to-parameter ratio $=12.3$.

In the crystal structure of the title salt, $\mathrm{C}_{8} \mathrm{H}_{11} \mathrm{~N}_{4} \mathrm{O}_{2}{ }^{+}$.$\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}_{3} \mathrm{O}_{7}^{-}$, the pictrate anion participates in extensive hydrogen bonding with the guanidinium ion group of the cation, linking the molecules through $\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}^{-}$hydrogen bonds and intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions. These hydrogen-bonding configurations involve two three-centre/bifurcated bonds $[\mathrm{N}-\mathrm{H} \cdots(\mathrm{O}, \mathrm{O})]$ that are observed between two N atoms from the guanidinium ion group of the cation and the $o-\mathrm{NO}_{2}$ and phenolate O atoms of the picrate anion. In addition, $\pi-\pi$ interactions also contribute to the crystal packing, with a centroid-to-centroid distance of 3.693 (6) $\AA$ and a slippage angle of $1.614^{\circ}$. A significant number of conformational differences are observed between the salt in the crystal structure and the models obtained by density functional theory (DFT) calculations of the geometryoptimized structure.

# 1-(2-Methyl-5-nitrophenyl)guanidinium picrate 

Jerry P. Jasinski, Ray J. Butcher, M. T. Swamy, H. S. Yathirajan and A. R. Ramesha

## S1. Comment

Guanidines, important compounds that have many biological, chemical and medicinal applications (Berlinck, 2002; Heys et al., 2000), have received increasing interest as medicinal agents with antitumour, antihypertensive, antiglaucoma and cardiotonic activities (Laeckmann et al., 2002; Kelley et al., 2001; Moroni et al., 2001). Due to their strong basic character, they can be considered as super-bases that readily undergo protonation to generate resonance-stabilized guanidinium cations (Ishikawa \& Isobe, 2002). Guanidine is used in variety of supramolecular recognition processes across the spectrum of organic, biological and medicinal chemistry (Orner \& Hamilton, 2001) with special interest motivated by their potential applications in non-linear optics (Zyss et al., 1993).
The crystal structures of a few related guanidine derivatives viz. guanidinium 2-amino-4-nitrobenzoate monohydrate at 130 K (Smith et al., 2007), (2,4,6-trinitrophenyl)guanidine (Smith et al., 2007a), 4-methoxy-phenylguanidinium chloride (Ren et al., 2007), (E)-1-[(2-methoxyphenyl)methyleneamino]guanidinium chloride (Sonar et al., 2007), have been reported. 1-(2-methyl-5-nitrophenyl)guanidine is one of the starting compounds for the synthesis of the anticancer drug, imatinib. In connection with the importance of guanidine derivatives, the present paper reports the crystal structure of the title compound, (I), $\mathrm{C}_{14} \mathrm{H}_{13} \mathrm{~N}_{7} \mathrm{O}_{9}$.
The title compound, (I), crystallizes as a salt with one independent cation-anion pair $\left[\mathrm{C}_{8} \mathrm{H}_{11} \mathrm{O}_{2} \mathrm{~N}_{4}{ }^{+} . \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}_{3} \mathrm{O}_{7}^{-}\right]$in the asymmetric unit (Fig. 1). Bond lengths and angles can be regarded as normal (Cambridge Structural Database, Version 5.30, February, 2009; Allen, 2002, Mogul, Version 1.1.3; Bruno et al., 2004). In the cation, the angle between the dihedral planes of the guanidinium ion $\left[\left(\mathrm{CH}_{5} \mathrm{~N}_{3}\right)^{+}\right]$and the bonded 2-methyl-5-nitrophenyl group is $83.0(7)^{\circ}$. All three nitrogen atoms ( $\mathrm{N} 2 \mathrm{~A}, \mathrm{~N} 3 \mathrm{~A} \& \mathrm{~N} 4 \mathrm{~A}$ ) exhibit $s p^{2}$ hybridization with a sum of angles around each atom of $360.0(0)^{\circ}$ resulting in a planar guanidinium ion group. The dihedral angle between the mean planes of the 5-nitro group and the benzyl ring is $5.0(3)^{\circ}$. In the picrate anion, the mean plane of two $o-\mathrm{NO}_{2}$ and single $p-\mathrm{NO}_{2}$ groups are twisted by $14.6(4)^{\circ}, 16.6(3)^{\circ}$ and $5.6(8)^{\circ}$, respectively, from the mean plane of the benzyl ring. The difference in the twist angles of the mean planes of the two $o-\mathrm{NO}_{2}$ groups can be attributed to an intermolecular hydrogen bonded interaction between the guanidinium ion of the cation with both of these groups ( $\mathrm{O} 21 \mathrm{~B}-\mathrm{N} 2 \mathrm{~B}-\mathrm{O} 22 \mathrm{~B} \& \mathrm{O} 61 \mathrm{~B}-\mathrm{N} 6 \mathrm{~B}-\mathrm{O} 62 \mathrm{~B}$ ) of the picrate anion, in which the O21B and O62B atoms form intermolecular "side" hydrogen bonds (N4A—H4AA $\cdots \mathrm{O} 21 \mathrm{~B}$ \& N3A-H3AB $\cdots \mathrm{O} 2 \mathrm{~B}$ ) with N4A and N3A from the guanidinium ion (Fig. 2, Table 1). N4A and N3A also both form intermolecular hydrogen bonds with the phenolate oxygen anion O1B (N4A—H4AA $\cdots \mathrm{O} 1 \mathrm{~B} \& \mathrm{~N} 3 \mathrm{~A}-\mathrm{H} 3 \mathrm{AB} \cdots \mathrm{O} 1 \mathrm{~B}$ ), each creating a bifrucated (threecentre), $\mathrm{N}-\mathrm{H} \cdots(\mathrm{O}, \mathrm{O})$ hydrogen bond. As a result, O 1 B and O 21 B act as the double acceptors. N4A and N3A form additional intermolecular hydrogen bonds with nearby O21B (N4A—H4AB $\cdots \mathrm{O} 21 \mathrm{~B})$ and O1A (N3A-H3AC $\cdots \mathrm{O} 1 \mathrm{~A})$ atoms, respectively. The dihedral angle between the mean planes of the benzyl ring and guanidinium ion group in the cation and the benzyl ring of the picrate anion are $80.8(7)^{\circ}$ and $7.4(7)^{\circ}$, respectively. Additional weak N2AH2AA $\cdots$ O22B and C3A—H3AA $\cdots$ O41B hydrogen bonds and $\pi-\pi$ stacking interactions occur ( $C g 1 \cdots C g 1=3.693$ (6) $\AA$; $x, 1-y,-z$; slippage $=1.614^{\circ} ; C g 1=\mathrm{C} 1 \mathrm{~A}-\mathrm{C} 6 \mathrm{~A}$ centroid) contributing to the stability of crystal packing.

A density functional theory (DFT) geometry optimization molecular orbital calculation (Schmidt \& Polik, 2007) was performed on the $\mathrm{C}_{8} \mathrm{H}_{11} \mathrm{O}_{2} \mathrm{~N}_{4}{ }^{+} \cdot \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{~N}_{3} \mathrm{O}_{7}{ }^{-}$cation-anion pair of the title molecule, (I), with the GAUSSIAN03 program package (Frisch et al. 2004) employing the B3LYP (Becke three parameter Lee-Yang-Parr) exchange correlation functional, which combines the hybrid exchange functional of Becke (Becke, 1988, 1993) with the gradient-correlation functional of Lee, Yang and Parr (Lee et al. 1988) and the 3-21G basis set (Hehre et al. 1986). Starting geometries were taken from X-ray refinement data. The dihedral angle between the dihedral planes of the guanidinium ion $\left[\left(\mathrm{CH}_{5} \mathrm{~N}_{3}\right)^{+}\right]$and the bonded 2-methyl-5-nitrophenyl group in the cation decreases by $7.1(2)^{\circ}$ to $70.9(1)^{\circ}$ while the mean plane of the 5nitro group decreases by $5.0(3)^{\circ}$ to become planar with the benzyl ring. In the picrate anion, the twist of the mean planes of two $o-\mathrm{NO}_{2}$ and single $p-\mathrm{NO}_{2}$ groups decreases by $12.3(1)^{\circ}, 10.4(9)^{\circ}$ and $5.6(8)^{\circ}$ to $4.3(2)^{\circ}, 4.1(5)^{\circ}$ and $0.0(0)^{\circ}$, respectively, from the mean plane of the 6-membered benzyl ring. The dihedral angle between the mean planes of the benzyl ring and guanidinium ion group in the cation and the benzyl ring of the picrate anion change by $-17.8(5)^{\circ}$ and $+2.1(9)^{\circ}$ to $63.0(2)^{\circ}$ and $9.6(6)^{\circ}$, respectively. Examination of the partial charges from the DFT geometry optimization indicate that H4AA (0.4.4384) is slightly more positive than $\mathrm{H} 3 \mathrm{~A}(0.402348)$ producing a slightly delocalized proton charge over the guanidium group and favoring the N4A atom. This coincides with a shorter N4A $-\mathrm{H} 4 \mathrm{AA} \cdots \mathrm{O} 1 \mathrm{~B}(=1.984$ $\AA$ ) hydrogen bond than $\mathrm{N} 3 \mathrm{~A}-\mathrm{H} 3 \mathrm{~A} \cdots \mathrm{O} 1 \mathrm{~B}(=2.033 \AA)$ due to the multiple acceptor function of O1B. In conclusion, the significant number of conformational changes that are observed between the crystalline environment of this cation-anion (1-(2-methyl-5-nitrophenyl)guanidinium picrate) salt and that of a density functional theory calculation of the geometry optimized structure support the effects of strong intermolecular hydrogen bonding interactions and weak $\pi-\pi$ ring intermolecular interactions between the guanidinium ion and bonded 2-methyl-5-nitrophenyl group of the cation and the $o-\mathrm{NO}_{2}, p-\mathrm{NO}_{2}$ and phenolate oxygen groups of the picrate anion as providing the major influence on packing effects in the crystal of the title compound, 1-(2-methyl-5-nitrophenyl)guanidinium picrate, (I).

## S2. Experimental

The title compound was synthesized by adding a solution of picric acid ( $0.92 \mathrm{~g}, 2 \mathrm{mmol}$ ) in 10 ml of methanol to a solution of 1-(2-methyl-5-nitrophenyl)guanidine ( $0.45 \mathrm{~g}, 2 \mathrm{mmol}$ ) in 10 ml of methanol (Scheme 2). A yellow colour developed and the solution was allowed to evaporate slowly at room temperature. The yellow colour compound formed was filtered off, washed several times with diethyl ether, and then dried over $\mathrm{CaCl}_{2}$ (yield: $64.2 \%$ ). Crystals for X-ray studies were grown by slow evaporation of dimethyl formamide solution. The melting range was found to be $382-385 \mathrm{~K}$. Analysis found (calculated) for $\mathrm{C}_{14} \mathrm{H}_{13} \mathrm{~N}_{7} \mathrm{O}_{9}$ (\%): C: 39.95 (39.72), H: 2.99 (3.1), N: 23.36 (23.16).

## S3. Refinement

All of the H atoms were placed in their calculated positions and then refined using the riding model with $\mathrm{N}-\mathrm{H}=0.88, \mathrm{C}$ $-\mathrm{H}=0.95 \AA$, and with $U_{\text {iso }}(\mathrm{H})=1.17-1.51 U_{\mathrm{eq}}(\mathrm{C}, \mathrm{N})$.

Figure 1
The asymmetric unit of $(\mathrm{I})$, showing the bifrucated (three-centre) $\mathrm{N}-\mathrm{H} \cdots(\mathrm{O}, \mathrm{O})$ donor hydrogen bond configuration and the atom labeling scheme. Hydrogen bonds are shown as dashed lines. Displacement ellipsoids are shown at the 50\% probability level.

Figure 2
Packing diagram of the title compound, (I), viewed down the $b$ axis. Dashed lines indicate intermolecular bifurcated (three-centre) $\mathrm{N}-\mathrm{H} \cdots(\mathrm{O}, \mathrm{O}), \mathrm{N}-\mathrm{H} \cdots \mathrm{O}$, and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ donor hydrogen bond interactions which produces a 2-D network arranged along the (101) plane.

## Special details

Experimental. CrysAlisPro, Oxford Diffraction Ltd., Version 1.171.33.34d (release 27-02-2009 CrysAlis171 .NET) (compiled Feb 27 2009,15:38:38) Empirical absorption correction using spherical harmonics, implemented in SCALE3 ABSPACK scaling algorithm.
Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\hat{A}^{2}$ )
