Received 30 October 2009; accepted 3 December 2009

Key indicators: single-crystal X-ray study; $T = 296\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; disorder in main residue; R factor = 0.042; wR factor = 0.109; data-to-parameter ratio = 15.0.

The title compound, $\text{C}_{33}\text{H}_{18}\text{F}_6$, has a V-shaped conjugated subunit. The dihedral angles between the central cyclopentene ring and the directly attached benzene rings are $32.7(2)$ and $53.7(2)^\circ$, respectively. The fluoro substituents are disordered, the occupancies refined to a $0.675(2):0.325(2)$ ratio.

Related literature

The title compound was synthesised with the aim of simulating the characteristics of so-called left-handed materials on a molecular scale. For a theoretical description of left-handed materials, see: Veselago (1968). For experimentally observed left-handed materials, see: Shelby *et al.* (2000); Chen *et al.* (2004); Zhou *et al.* (2006); Zhang *et al.* (2005); Liu *et al.* (2007).

S1. Comment

Left-handed material is a kind of material that exhibits a negative refraction index. It has been explored theoretically by Veselago (1968). In 2000, a two-dimensional isotropic left-handed material was verified showing a negative refraction index (Shelby *et al.*, 2000). From then on, the study of left-handed materials has gained increasing interest in physics-related fields. So far, most of the left-handed materials were realised *via* micro-processing technologies to integrate a metal into a S-shape (Chen *et al.*, 2004) or H-shape (Zhou *et al.*, 2006) micro-structural unit, therefore achieving a periodic arrangement. However, due to the technology limitations of nano-scale processing technology, most of the successful experimental verification are carried out in the microwave band (Zhang *et al.*, 2005; Liu *et al.*, 2007). Only if the left-handed material structural unit achieves a smaller size, a negative refraction index might be realised in the visible range. Using concepts of chemical synthesis technology to create structural features of left-handed materials at the molecular level might show potential to realise negative refraction in the visible range. The molecular model should exhibit an extended conjugated system providing electrons that are easily excited.

In this article, we tried to simulate structural features of left-handed material and designed a V-shaped conjugated organic molecular structure (Fig. 1). The title compound turns out to be a single-crystal, but whether it is really close to the structural features of left-handed materials or not and how to modify it to exhibit negative refraction, is still under investigation. The dihedral angle between the benzene ring C9—C14 and the adjacent benzene ring C1—C6 is 31.4 (1) °, the dihedral angle between the benzene ring C23—C28 and the adjacent benzene ring C15—C20 is 50.7 (2) °. C7—C8 (1.192 (2) Å) and C21—C22 (1.188 (2) Å) are acetylenic bonds and are therefore significantly shorter than the other carbon carbon bonds. The fluoro substituents at the cyclopentene ring are disordered with occupancies refined to a 0.675 (2):0.325 (2) ratio.

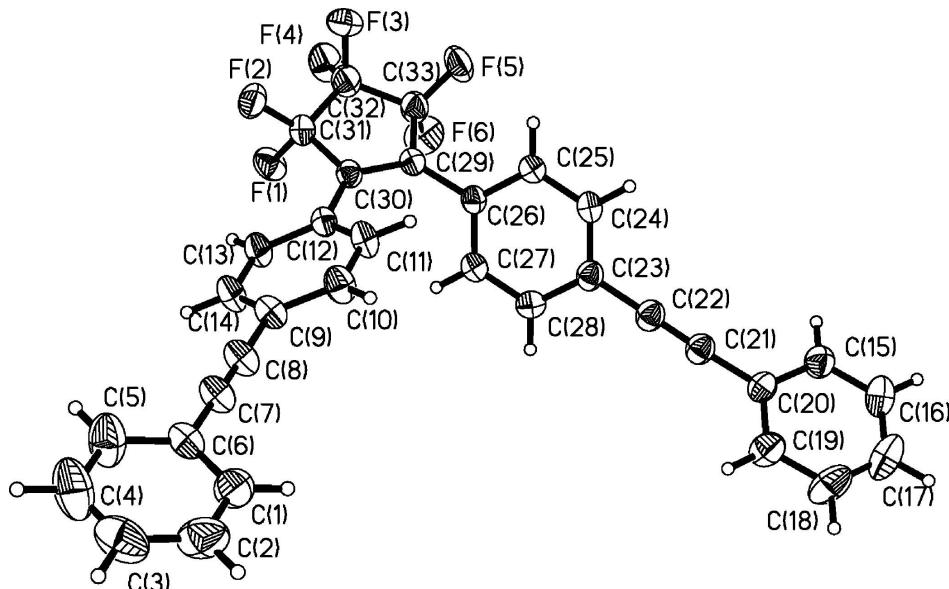

S2. Experimental

Synthesis of the title compound was carried out in two steps:(1) 4-bromo-1-phenylethynylbenzene, was obtained in 72.6% yield by the reaction of phenylacetylene (12 g, 0.1 mol) and 1-Bromo-4-iodobenzene (28.29, 0.1 mol) in $N(C_2H_5)_3$ (150 ml) solution catalyzed by CuI (0.3 g, 1.55 mmol), PPh₃ (0.6 g, 2.45 mmol) and Pd(PPh₃)Cl₂(0.3 g, 0.42 mmol) at 336 K; (2) 1.6 ml of n-BuLi/hexane solution (2.5 mol/L, 4.0 mmol) was added slowly at 195 K under a nitrogen atmosphere to a stirred THF solution (40 ml) containing 4-bromo-1-phenylethynylbenzene (1.03 g, 4 mmol). After 30 min perfluorocyclopentene (0.27 ml, 2 mmol) was added and the mixture was stirred for 1 h at this temperature. The reaction mixture was extracted with CHCl₃, evaporated *in vacuo* and purified by column chromatography (hexane) to give the title compound. After recrystallization from CH₂Cl₂ light yellow-green crystals of the title compound were obtained in 23.4% yield.

¹HNMR (400 MHz, CDCl₃): δ 7.35(m, 10H), 7.51 (m, 8H)

S3. Refinement

All H atoms attached to C were fixed geometrically and treated as riding with C—H = 0.93 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. The occupancies of the disordered components refined to a 0.675 (2):0.325 (2) ratio for F1:F1', F2:F2', F3:F3', F4:F4' F5:F5' and F6:F6'.

**Figure 1**

Molecular structure showing the atom-labelling scheme. Ellipsoids are drawn at the 30% probability level. H atoms are represented as small spheres of arbitrary radii.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
