Received 16 February 2010; accepted 23 February 2010

Key indicators: single-crystal X-ray study; $T = 295\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.007\text{ \AA}$; R factor = 0.020; wR factor = 0.048; data-to-parameter ratio = 11.8.

In the crystal structure of the title compound, $[\text{Pb}_2(\text{C}_4\text{H}_5\text{NO}_4)_2(\text{C}_6\text{H}_6\text{N}_4\text{S}_2)_2] \cdot 4\text{H}_2\text{O}$, the dinuclear Pb^{II} complex molecule is centrosymmetric. The Pb atom is chelated by a tridentate iminodiacetate anion (IDA) and a diaminobithiazole (DABT) ligand, while a carboxylate O atom from an adjacent IDA anion further bridges the Pb atom with a longer $\text{Pb}-\text{O}$ bond [2.892 (3) \AA]. The lone-pair electrons of the Pb atom occupy an axial site in the Ψ -pentagonal-bipyramidal coordination polyhedron. The IDA anion displays a facial configuration: its chelating five-membered rings assume an envelope configuration. Within the DABT ligand, the two thiazole rings are twisted relative to each other, making a dihedral angle of 9.51 (17) $^\circ$. Extensive $\text{N}-\text{H}\cdots\text{O}$, $\text{O}-\text{H}\cdots\text{O}$ and weak $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonding helps to stabilize the crystal structure.

Bis(μ -iminodiacetato)bis[(2,2'-diamino-4,4'-bi-1,3-thiazole)lead(II)] tetrahydrate

Mei Du, Bing-Xin Liu, Jing-Jing Nie and Duan-Jun Xu

S1. Comment

Some metal complexes with 2,2'-diamino-4,4'-bi-1,3-thiazole (DABT) have shown the potential application in the biological field (Waring, 1981; Fisher *et al.*, 1985). As a part of serial structural investigation of metal complexes with DABT, the title Pb^{II} complex was prepared in the laboratory and its X-ray structure is presented here.

The molecular structure of the title compound is shown in Fig. 1. The dinuclear Pb^{II} complex molecule is centrosymmetric. Each Pb atom is chelated by a tridentate iminodiacetate anion (IDA) and a diaminobithiazole (DABT) ligand, and one carboxyl O atom from the adjacent IDA anion further bridges the Pb atom. The lone-pair electrons of the Pb atom occupy an axial site in the distorted Ψ -pentagonal bipyramidal coordination geometry, which is similar to that found in Pb^{II} complexes reported previously (Lacouture *et al.*, 2001; Jones *et al.*, 1988). The longer Pb—O(bridge) bond distance (Table 1) is comparable to 2.968 (4) Å found in a related Pb complex (Inoue *et al.*, 1993). The IDA displays a facial configuration, its both chelating five-membered rings assume the envelope configuration. Within the DABT ligand, the two thiazole rings are twisted to each other with a dihedral angle of 9.51 (17) $^{\circ}$, it agrees with 14.7 (3) and 9.5 (2) $^{\circ}$ found in transition metal complexes of DABT (Liu *et al.*, 2006; Zhang *et al.*, 2006).

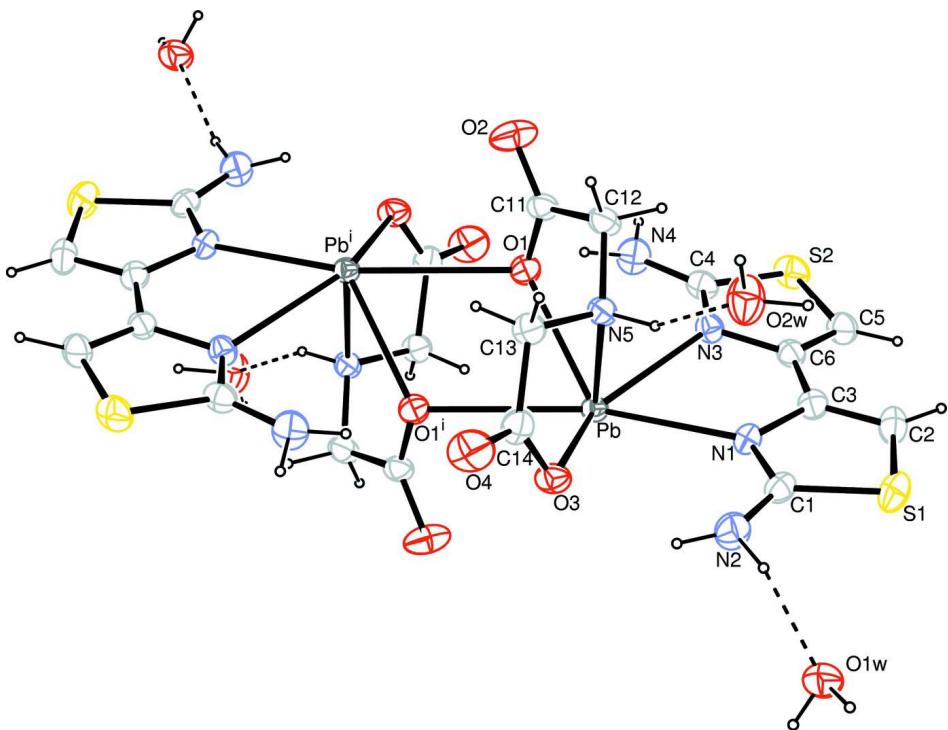

The extensive N—H···O, O—H···O and weak C—H···O hydrogen bonding helps to stabilize the crystal structure (Table 2).

S2. Experimental

An aqueous solution (20 ml) containing DABT (0.20 g, 1 mmol) and Pb(NO₃)₂ (0.33 g, 1 mmol) was mixed with another aqueous solution (10 ml) of H₂IDA (0.13 g, 1 mmol) and NaOH (0.08 g, 2 mmol). The mixture was refluxed for 5 h. The solution was filtered after cooling to room temperature. Single crystals were obtained from the filtrate after one week.

S3. Refinement

H atoms bonded to N and O atoms were located in a difference Fourier map and were refined with distance constraints [O—H = 0.82±0.03 and N—H = 0.86±0.03 Å] and U_{iso}(H) = 0.08 Å². H atoms on carbon atoms were placed in calculated positions with C—H = 0.97 Å (methylene) and 0.93 Å (aromatic), and included in the final cycles of refinement in the riding model with U_{iso}(H) = 1.2U_{eq}(C).

**Figure 1**

The dinuclear molecular structure with 30% probability displacement ellipsoids. Dashed lines indicate the hydrogen bonding [symmetric code: (i) $-x, -y, 1-z$].

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
