Received 13 June 2010; accepted 2 July 2010

Key indicators: single-crystal X-ray study; $T = 150$ K; mean $\sigma(C-C) = 0.008$ Å; R factor = 0.051; wR factor = 0.095; data-to-parameter ratio = 14.8.

In the centrosymmetric binuclear title compound, $[Zn_2Cl_4(C_{20}H_{17}N_3)_2]$, the coordination geometry of the Zn^{II} ion can be described as a distorted ZnN_2Cl_3 trigonal bipyramidal ($\tau = 0.89$), arising from the *N,N*-bidentate ligand, a terminal chloride ion and two bridging chloride ions. The N atoms occupy one axial and one equatorial site and the terminal chloride ion occupies an equatorial site. The dihedral angle between the pyridine and pyrazole rings is 12.8 (2)°. In the crystal, aromatic $\pi-\pi$ stacking [centroid–centroid separations = 3.812 (3) and 3.848 (3) Å] and C–H···Cl and C–H···π interactions help to establish the packing.

Di- μ -chlorido-bis{chlorido[(R)/(S)-1,5-diphenyl-3-(2-pyridyl- κ N)-2-pyrazoline- κ N²]zinc(II)}

Miquel Barceló-Oliver, Angel Terrón, Angel García-Raso, Iztok Turel and Marta Morell

S1. Comment

The interest in Zn^{II} detection is due to the importance of this cation in living systems, because is the second (following iron) most abundant transition metal ion in human body (Casas *et al.*, 2002). The fact that the Zn^{II} is a d¹⁰ ion, diamagnetic and lacking d-d electronic transitions precludes usual techniques as electronic spectroscopy, e.p.r. or magnetic measurements for studying its compounds. Moreover, the major naturally occurring isotopes have zero nuclear spin and thus, the ion is NMR silent. For these reasons fluorescent probes to determine the "free" or "available" zinc(II) concentrations in living systems should be useful alternatives.

Due to their inner fluorescence properties, 1,3,5-triaryl-²Δ-pyrazolines have been utilized as fluorescence probes in some elaborated chemosensors (Bissell *et al.*, 1993 and Silva *et al.*, 1997). On the other hand, the fluorescent 3-(2-pyridyl) analogues of triarylpyrazolines themselves can serve as N,N'-type bidentate ligands for metal ions. Wang *et al.* (2001) have reported that pyridylpyrazoline derivatives show specific fluorescent behaviour towards the Zn²⁺ ion among divalent transition metal ions, specially for the 5-(4-cyanophenyl)-1-phenyl-3-(2-pyridyl)-²Δ-pyrazoline derivative. Stability constant in acetonitrile for the ZnL₂ complex was determined as 3.4 10¹¹ with a clear selectivity to other divalent ions as copper(II) (Wang *et al.*, 2001). Nevertheless, no references exist in the literature related to structural studies of this type of compounds and metal ions, except for the ternary complex of bis-(2,2'-bipyridyl)ruthenium(II) and a non-fluorescent pyrazoline analogue, the 1-phenyl-3-(2-pyridyl)-5-(4-nitrophenyl)-²Δ-pyrazoline (refcode XOCXIW, Wang *et al.*, 2001) with no coordinates available at Cambridge Structural Database (CSD, Version 5.31, February 2010 update; Allen, 2002). In the present paper, a crystallographic study of the Zn^{II} complex of the fluorescent ligand 1,5-di-phenyl-3-(2-pyridyl)-²Δ-pyrazoline (Barceló-Oliver *et al.*, 2010) is performed.

A comparison between the previously described ligand (Barceló-Oliver *et al.*, 2010) and its Zn^{II} complex permits to observe a conformational modification related to the pyridine-pyrazoline moiety, where the s-trans conformation found in the ligand changes to a s-cis disposition in the complex (See Fig. 1). This feature is common in 2,2'-bipyridyl ligands.

Contrarily to previously mentioned 1:2 ZnL₂ complex (Wang *et al.*, 2001) in our hands, reaction between ZnCl₂ and 1,5-diphenyl-3-(2-pyridyl)-²Δ-pyrazoline only yields a dimeric 1:1 [(LZnCl)₂Cl₂] compound. {Zn(Cl)((R)-1,5-diphenyl-3-(2-pyridyl)-²Δ-pyrazoline)}(μ -Cl){Zn(Cl)((S)-1,5-diphenyl-3-(2-pyridyl)-²Δ-pyrazoline)} (I) crystallizes as a dimer with an inversion center between the chloride ligands relating the two monomers. We have not isolated any ZnL₂ complex, contrarily to what happen with Zn^{II} and 1,10-phenanthroline or 2,2'-bipyridyne, which have stability constants about 1 10¹⁷ and 2 10¹³ respectively (Yamasaki & Yasuda, 1956).

The dimer is formed through two bridged chlorido anions linked with long (Zn1–Cl2) and short (Zn1–Cl2ⁱ) distances to the Zn^{II} metal ions (see Fig. 2 and Table 1). Moreover, pyridine (Zn1–N32) and imino (Zn1–N2) nitrogen atoms and a monodentate chloride ligand (Zn1–Cl1) are coordinated to both metal ions. The geometry around the metallic ion is

described by means a distorted trigonal bipyramidal [$\tau = 0.89$ (Addison *et al.*, 1984)]. The bite distance between the two bonding nitrogen atoms is 2.716 (7) Å and the dihedral angle between the pyridyl and the pyrazolyl planes is 12.8°.

Within the dimeric complex unit, some hydrogen bonds are found with the chlorine atoms as acceptors: C5 from the pyrazoline ring interacts with Cl1ⁱ, C12 from the phenyl ring bonded to N1 is in contact with Cl1 and C33 from the pyridine ring interacts with Cl2 (see Table 2 for more details). More in detail, the second hydrrogen bond (C12–H12···Cl1) forces the twist of the phenyl ring respect to the pyrazoline mean plane (N1–C11 bond): the structure of the ligand (Barceló-Olivier *et al.*, 2010) presents an angle between mean planes of 3.47° while this value is 19.63° in the Zn^{II} complex.

On the other hand, two pyrazoline ligands of adjacent complex units form a centrosymmetric couple along the *b* direction of the crystal by means of two C–H···π interactions between pyridine rings, with C34 as donors, and phenyl rings bounded to C5, corresponding to two different molecules (Table 3 and Fig. 3). This interaction yields a one-dimensional chain thorugh the crystal which is also reinforced with intramolecular π–π interactions (Table 4). To complete the structure of the crystal, two-dimensional planes are formed by means of weaker interactions relating the already described one-dimensional chains among them.

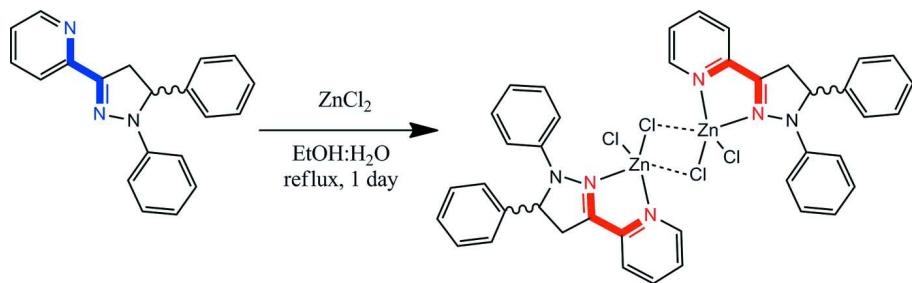

This Zn^{II} complex is soluble in chloroform and presents a distinctive fluorescence in this solvent ($\lambda_{\text{exc}} = 384$ nm and $\lambda_{\text{em}} = 480$) related to the previously described ligand [$\lambda_{\text{exc}} = 397$ nm and $\lambda_{\text{em}} = 464$ nm (Barceló-Olivier *et al.*, 2010)]. For this reason, this ligand could be useful for Zn^{II} determination in low dielectric constant media. No fluorescence is observed with other metal ions such as Cu(II), Ag(I) and Cd(II), which is in agreement to previous literature data (Wang *et al.*, 2001), possibly due to a metal quenching.

S2. Experimental

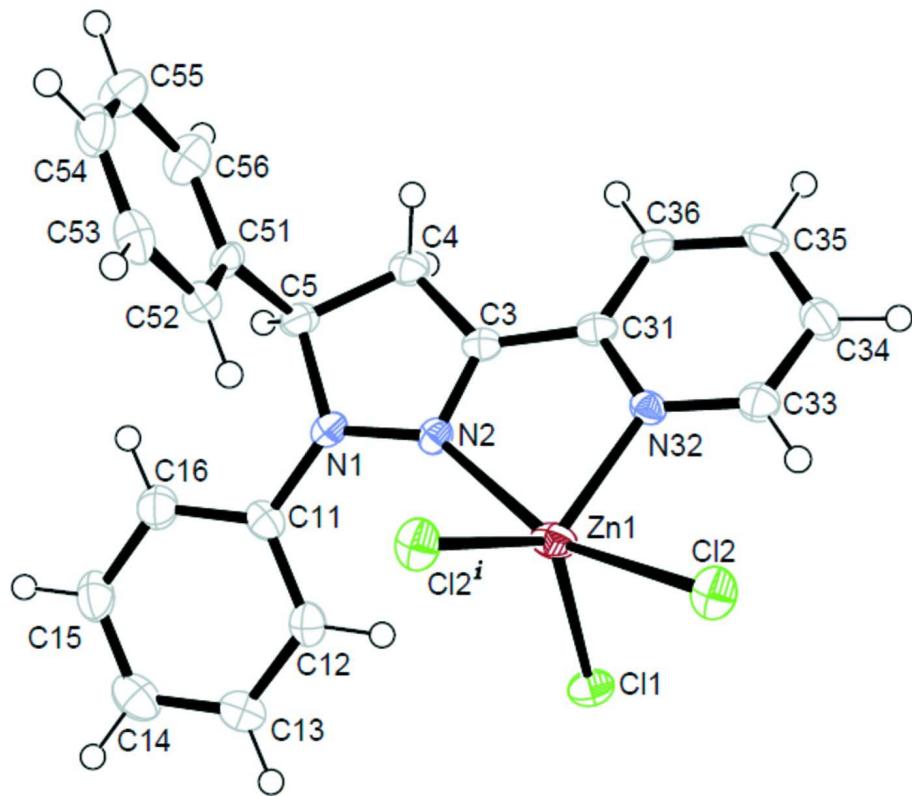

1,5-diphenyl-3-(2-pyridyl)-²Δ-pyrazoline (2 mmol) and ZnCl₂ (1 mmol) were suspended in 60 ml EtOH/H₂O (50:50) and refluxed for 24 h. The solution was filtered off and left to crystallize. Orange microcrystals were obtained after 2–3 days [yield: 45%]. The complex was recrystallized from acetonitrile and orange hexagonal rods of (I) were obtained. *Anal.*

Special details

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
