Received 21 June 2010; accepted 25 June 2010

Key indicators: single-crystal X-ray study; T = 293 K; mean σ(C–C) = 0.004 Å; R factor = 0.037; wR factor = 0.098; data-to-parameter ratio = 22.9.

The asymmetric unit of the title compound, $(C_{10}H_{28}N_4)[CoCl_4]Cl_2$, contains two half-molecules of the macrocycle, which are both completed by crystallographic inversion symmetry. In the dianion, the Co^{2+} cation is tetrahedrally coordinated by four Cl atoms; the Co—Cl bond lengths correlate with the number of hydrogen bonds that the chloride ions accept. The crystal cohesion is supported by electrostatic interactions which, together with numerous N—H⋯Cl, N—H⋯(Cl,Cl) and C—H⋯Cl hydrogen bonds, lead to a three-dimensional network.

S1. Comment

The rational design and synthesis of organic-inorganic hybrid materials have attracted an increasing interest in recent years not only from a structural point of view, but also due to their potential applications in different areas such as catalysis, medicine, electrical conductivity, magnetism and photochemistry (e.g. Bu *et al.*, 2001).

A large number of transition metal when associated to organic molecule which presents potential sites of the hydrogen bonding interactions, exhibit interesting one- (1-D), two- (2-D), and three-dimensional (3-D) structures. These organic molecules may be present different and interesting properties which can profoundly influence the structures of inorganic component in the resultant hybrid material. Such organic-inorganic hybrid materials can combine appropriate characteristics of each component to produce novel structural types, as well as new properties arising from the interplay of the two components (Mitzi *et al.*, 1999).

The asymmetric unit of the $[CoCl_4](C_{10}H_{28}N_4),2Cl$, (I). contains one tetrachlorocobalt anion, one organic cation and two chloride anion as shown in Fig. 1. The cohesion and the stability between these different components are assured by the network hydrogen bonding of type (N—H···Cl). However, the energetic of N—H···Cl—*M* (*M* = metal) hydrogen bonds and their possible roles in supramolecular chemistry have only been recently described in details (Brammer *et al.*, 2002). This type of hydrogen bond is also observed in other hybrid compounds such as Bis(5-Chloro-2,4-Dimethoxyanilinium) Tetrachlorozincate Trihydrate (El Glaoui *et al.*, 2009) and pyrrolidinium hexachloroantimonate (V) (Jakubas *et al.*, 2005).

The Co^{2+} entity is tetrahedrally coordinated to four chloride atoms as shown in Figure 2. The distortion from the ideal geometry is small. This situation is also observed in others compounds which contain $CoCl_4^{2-}$ entity as an anion (Adamski *et al.*, 2009). Examination of the $CoCl_4^{2-}$ geometry shows two types of Co—Cl distances. The largest ones 2.3170 (8) Å, 2.2963 (7) Å and 2.2950 (9) Å, while the smallest one is 2.2609 (8) Å. The average values of the Co—Cl distances and Cl—Co—Cl angles are 2.2923 Å and 109.52°, respectively. These geometrical features have also been noticed in others crystal structure (Boyd *et al.*, 2007); (Hashizume *et al.*, 1999).

The differences in the Co—Cl bond lengths correlate with the number of hydrogen bonds accepted by the Cl atom: Co—Cl4 bond is the longest (2.3170 (8) Å); Cl4 accepts three H-bonds, Co—Cl2 and Co—Cl3 have similar, intermediate lengths, and Cl1, which accepts only C—H···Cl hydrogen bond, makes the shortest Co—Cl bond.

The four N atoms of the macrocyclic ring are protonated, which provide the cations as formula $(C_{10}H_{28}N_4)^{4+}$, for neutralize the negative charge of the anionic part. Crystal cohesion and stability are supported by electrostatic interactions which, together with N—H···Cl and C—H···Cl hydrogen bonds, build up a three-dimensional network.

S2. Experimental

The hexahydrate of chloride cobalt (II) $CoCl_2.6H_2O$ (3.1 mmol) was added to an aqueous solution containing a stochiometric ratio of $C_{10}H_{24}N_4$ (1,4,8,11-tetraazacyclotetradecane) (3.1 mmol) under continuous stirring. A pink precipitate was formed, which was completely dissolved by adding an aqueous solution of HCl until it disappeared. The obtained solution was slowly evaporated at room temperature for several days until the formation of blue prisms of (I). The synthesis is reproducible and crystals obtained in this way are stable for a long time under normal conditions of temperature and humidity.

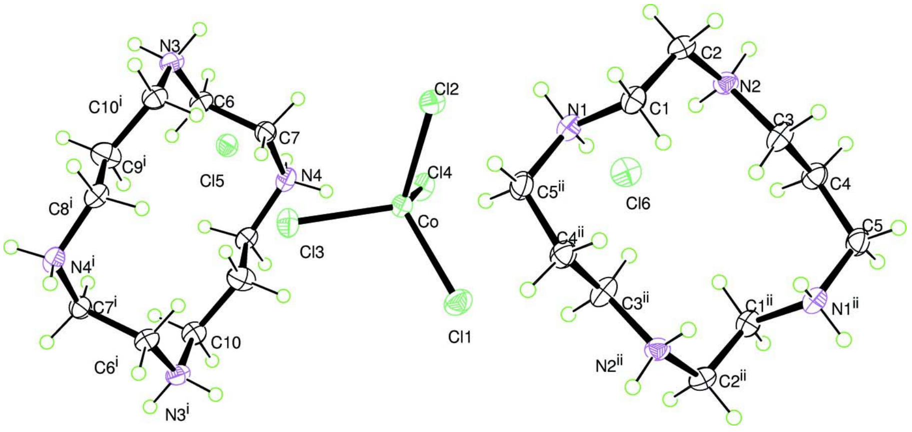

Figure 1

The molecular structure of (I): displacement ellipsoids are drawn at the 30% probability level. H atoms are represented as spheres of arbitrary radius. [Symmetry code: (i) (-*x* + 1, -*y* + 1, -*z* + 1))(ii) (*x*, -1 + *y*, *z*)].

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2, conventional R-factors R are based on F, with F set to zero for negative F^2. The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R-factors(gt) *etc*. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
