Received 26 August 2010; accepted 8 September 2010

Key indicators: single-crystal X-ray study; $T = 295$ K; mean $\sigma(C-C) = 0.008$ Å; disorder in main residue; R factor = 0.023; wR factor = 0.059; data-to-parameter ratio = 9.7.

In the centrosymmetric title compound, $[Gd_2(C_6H_8O_4)(C_2O_4)_2(H_2O)_2]_n$, the Gd^{3+} cations are each coordinated by nine O atoms, three from adipate anions, two from oxalate anions and one from an aqua ligand, completing a distorted tricapped trigonal-prismatic geometry. These tricapped trigonal prisms are bridged by the adipate ligands, generating layers lying parallel to (010). The coordination polymer layers are linked into a three-dimensional framework by the rigid oxalate ligands. The adipate and oxalate ions are all located on centers of inversion. A part of the adipate anion is disordered over two positions in a 0.75:0.25 ratio.

S1. Comment

As shown in Fig. 1 the asymmetric unit of the title compound consists of one Gd^{3+} cation, half of an adipate anion, two half oxalate anions and one aqua ligand. The Gd atom is coordinated by nine oxygen atoms, in which four oxygen atoms are from three adipate anions, four from two oxalate anions and one from a water molecule, to form a SmO_9 polyhedron with a distorted tricapped trigonal-prismatic geometry. The Gd—O(adipate) distances vary in the range of 2.430 (4)–2.575 (4) Å (average 2.512 (4) Å), which is nearly identical to the value of 2.425 (8)–2.611 (8) Å (average 2.471 (8) Å) observed in $\text{Gd}_2(\text{C}_6\text{H}_8\text{O}_4)_3(\text{H}_2\text{O})_4$ (Dimos *et al.*, 2002). The Gd—O(oxalate) distances are in the range of 2.385 (4)–2.540 (4) Å, which are usual for lanthanide oxalates complexes (Trombe & Mohanu, 2004). In the title complex, the adipate anions are located on inversion centers and atom C3 is positionally disordered (C3A and C3B; occupancies 0.75/0.25). Two carboxylate oxygen atoms chelate one Gd atom with each oxygen atom additionally bonded to another Gd atom. To the best of our knowledge, this $\eta^2,\mu_3\text{-}\eta^2,\mu_3$ -chelating-bridging octadentate coordination mode of the adipate ligand has not been reported previously.

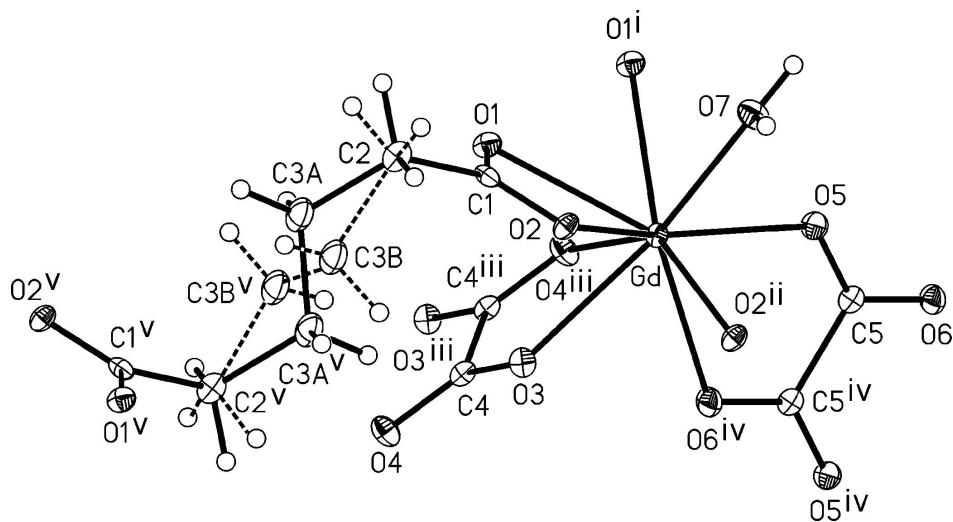

Through the terminal carboxylato bridging interactions, the GdO_9 polyhedra are edged-shared to generate metal-oxygen chains extending infinitely along [100], in which the adjacent $\text{Gd}\cdots\text{Gd}$ distances are 4.23 (3) Å and 4.25 (2) Å, respectively. Along [001] the chains are linked by the adipate anions into layers parallel to (010) (Fig. 2). Two symmetry independent oxalate ions are also located on centers of inversion and act as double bidentate (tetradeятate) ligands in a linear chain, which connect Gd atoms to form zigzag chains along [001]. Through the oxalate and adipate ligand bridging interactions, the Gd atoms build up a three-dimensional open framework with the channels propagating in [001] (Fig. 3). The aqua ligand provides H-bond donors which participate in O-H···O hydrogen bonds with the oxalate atoms O3 and O6 (Table 1).

S2. Experimental

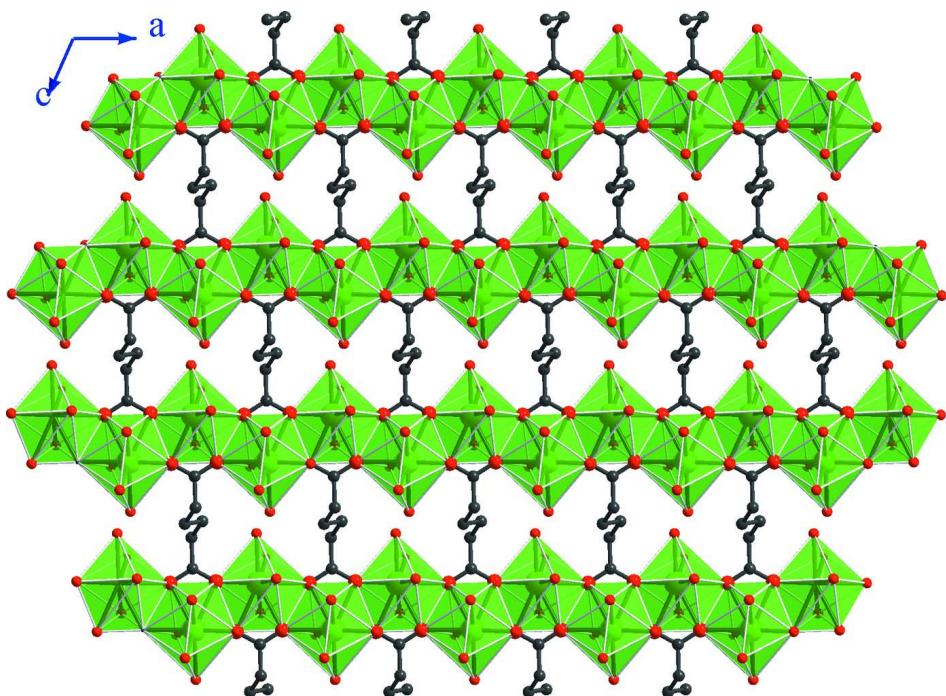

A mixture of $\text{GdCl}_3\cdot 6\text{H}_2\text{O}$ (1.00 mmol, 0.36 g), oxalic acid (0.50 mmol, 0.05 g), adipic acid (0.50 mmol, 0.07 g), NaOH (2.00 mmol, 0.08 g) and H_2O (10.0 ml) was heated in a 23 ml stainless steel reactor with a Teflon liner at 443 K for 48 h. On cooling a small amount of colorless plate-like crystals were obtained. They were filtered off and washed with water and acetone.

S3. Refinement

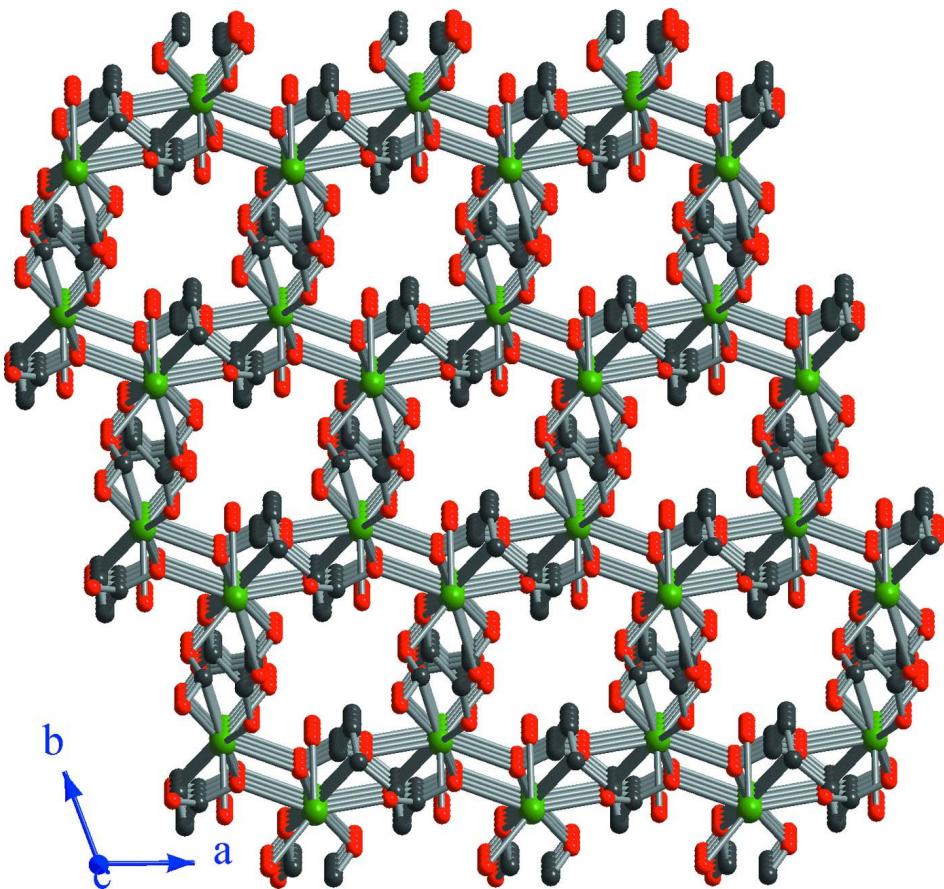

Atom C3 of the adipate anion is positionally disordered (C3A and C3B) and these atoms were refined with occupancies of 0.75/0.25. The water H-atoms were located in difference Fourier maps and were refined with distance restraints: O—H distance of 0.84 (2) Å and $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$. The C-bound atoms were included in calculated positions and treated as riding atoms: C—H = 0.97 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. The highest density peak and deepest hole are located at 0.97 Å and 0.89 Å, respectively, from the Gd atom.

**Figure 1**

The fragment of the molecular structure of the title compound, with the atom-numbering scheme. Displacement ellipsoids are drawn at the 30% probability level and H atoms are shown as small spheres of arbitrary radii. Symmetry codes: (i) $-x, 1 - y, 1 - z$; (ii) $1 - x, 1 - y, 1 - z$; (iii) $-x, -y, 1 - z$; (iv) $-x, -y, -z$; (v) $1 - x, 1 - y, 2 - z$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
