Correspondence e-mail: mweil@mail.zserv.tuwien.ac.at

The title compound, Cd$_2$P$_4$O$_{12}$, dicadmium *cyclo*-tetra-phosphate, crystallizes isotypically with the members of the series M^{II}_2P$_4$O$_{12}$, where *M* = Mg, Mn, Fe, Co, Ni or Cu. Two CdO$_6$ octahedra, one with 2 and one with $\bar{1}$ symmetry, share corners with the centrosymmetric P$_4$O$_{12}{}^{4-}$ ring anion that is built up from four corner-sharing PO$_4$ tetrahedra. The isolated ring anions are arranged in layers parallel to (10$\bar{1}$) with the CdO$_6$ octahedra situated between these layers. The main difference between the individual M^{II}_2P$_4$O$_{12}$ structures pertains to the different sizes of the MO$_6$ octahedra whereas the geometric parameters of all *cyclo*-P$_4$O$_{12}{}^{4-}$ anions are very similar.

Related literature

For a previous powder X-ray study of Cd$_2$P$_4$O$_{12}$, see: Laügt *et al.* (1973). The structure of the low-temperature α-modification of the *catena*-polyphosphate Cd(PO$_3$)$_2$ was refined by Bagieu-Beucher *et al.* (1974). For isotypic M^{II}_2P$_4$O$_{12}$ structures, see: Nord & Lindberg (1975) for *M* = Mg; Glaum *et al.* (2002) for Mn; Nord *et al.* (1990) and Genkina *et al.* (1985) for Fe; Nord (1982) and Olbertz *et al.* (1998) for Co; Nord (1983) and Olbertz *et al.* (1998) for Ni; Laügt *et al.* (1972) for Cu. A review on the crystal chemistry of phosphates was published by Durif (1995). Ionic radii were compiled by Shannon (1976).

supporting information

The *cyclo*-tetraphosphate Cd$_2$P$_4$O$_{12}$, a member of the isotypic series M_2P$_4$O$_{12}$ (M = Mg, Mn, Fe, Co, Ni, Cu)

Matthias Weil

S1. Comment

M^{II}_2P$_4$O$_{12}$ compounds containing the *cyclo*-tetraphosphate anion P$_4$O$_{12}^{4-}$ have been the subject of numerous crystallographic studies. Except for Cd$_2$P$_4$O$_{12}$ (X-ray powder data; Laügt *et al.*, 1973), detailed structure data are available for Mg$_2$P$_4$O$_{12}$ (Nord & Lindberg, 1975), Mn$_2$P$_4$O$_{12}$ (Glaum *et al.*, 2002), Fe$_2$P$_4$O$_{12}$ (Nord *et al.*, 1990; Genkina *et al.*, 1985), Co$_2$P$_4$O$_{12}$ (Nord, 1982; Olbertz *et al.*, 1998), Ni$_2$P$_4$O$_{12}$ (Nord, 1983; Olbertz *et al.*, 1998) and Cu$_2$P$_4$O$_{12}$ (Laügt *et al.*, 1972). During experiments intended for crystal growth of large single crystals of the low-temperature modification of cadmium *catena*-polyphosphate, α-Cd(PO$_3$)$_2$ (Bagieu-Beucher *et al.*, 1974), single crystals of the title compound were obtained instead.

The crystal structures of the isotypic M^{II}_2P$_4$O$_{12}$ family are built up from centrosymmetric P$_4$O$_{12}^{4-}$ ring anions. The isolated anions are arranged in layers parallel to (10$\bar{1}$). Two sets of slightly distorted MO$_6$ octahedra, one with $\bar{1}$ symmetry and one with 2 symmetry, share edges and are situated in the interlayer space. The three-dimensional framework is accomplished by corner-sharing of the MO$_6$ units and the P$_4$O$_{12}^{4-}$ anions. Figures 1 and 2 show the resulting arrangement for Cd$_2$P$_4$O$_{12}$.

The P$_4$O$_{12}^{4-}$ ring anion of Cd$_2$P$_4$O$_{12}$ (Fig. 3) consists of four corner-sharing PO$_4$ tetrahedra and shows the typical features with respect to bond lengths and angles, *i.e.* shorter terminal P—O bonds and longer P—O bonds to the bridging O atoms. A review on structures containing the *cyclo*-tetraphosphate anion has been given by Durif (1995) where characteristic distances and angles are compiled. The individual bond lengths and angles of the P$_4$O$_{12}^{4-}$ anions are very similar in all M^{II}_2P$_4$O$_{12}$ structures. The main difference between the structures is related to the varying ionic radii of the M^{II} cations. Correspondingly, the MO$_6$ octahedra show (slight) variations in the M—O bond lengths. In the M^{II}_2P$_4$O$_{12}$ family (M = Mg, Mn, Fe, Co, Ni, Cu, and Cd), Cd^{II} has the largest ionic radius (0.95 Å) for coordination number 6 (Shannon, 1976). This value seems to be the upper limit for the existence of the M^{II}_2P$_4$O$_{12}$ family of structures. For larger M^{II} cations like Hg^{II} or Pb^{II} (ionic radius 1.02 Å and 1.19 Å, respectively) solely long-chain *catena*-polyphosphate structures M(PO$_3$)$_2$ are realised.

In the review on condensed phosphates given by Durif it was stated that *cyclo*-Cd$_2$P$_4$O$_{12}$ transforms irreversibly into the low-temperature α-modification of the long-chain polyphosphate Cd(PO$_3$)$_2$ by prolonged heating at 573 K (Durif, 1995, and references therein), indicating that this transformation process is kinetically controlled. This assumption is confirmed by DSC (differential scanning calorimetry) measurements of the current sample (N$_2$ atmosphere, heating rate 10 K·min^{-1}). Whereas no phase transition has been observed for this compound up to 873 K under these conditions, heating the sample at 873 K in a laboratory furnace under atmospheric conditions for 20 h resulted in a complete transformation into α-Cd(PO$_3$)$_2$.

S2. Experimental

Single crystals suitable for X-ray structure analysis were grown using the phosphate flux method. CdO (0.7 g) was placed in a glassy carbon crucible and was covered carefully with $70\%_{wt}$ H_3PO_4 (5.4 g). The crucible was subjected to the following temperature programme: RT → 693 K [3 h] → 693 K [5 h] → 573 K [48 h]. Then the crucible was removed from the furnace. Prismatic colourless crystals with maximum edge lengths of 1.5 mm were obtained by leaching the phosphate flux with warm water.

S3. Refinement

The highest peak in the final Fourier map is located 0.62 Å from Cd2 and the deepest hole is 0.96 Å from the same atom.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2, conventional R-factors R are based on F, with F set to zero for negative F^2. The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R-factors(gt) *etc*. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
