Received 11 November 2010; accepted 18 November 2010

Key indicators: single-crystal X-ray study; $T = 116$ K; mean $\sigma(C-C) = 0.003$ Å; disorder in solvent or counterion; R factor = 0.024; wR factor = 0.051; data-to-parameter ratio = 14.8.

The reaction of 2-acetylpyridine with silver(I) tetrafluoridoborate leads to the discrete title complex, $[\text{Ag}(\text{C}_7\text{H}_7\text{NO})_2]\text{BF}_4$, in the cation of which the Ag atom is coordinated by two 2-acetylpyridine ligands, each of which is N,O -bidentate, albeit with stronger bonding to the N atoms [Ag—N = 2.2018 (15) and 2.2088 (14) Å; Ag—O = 2.5380 (13) and 2.5454 (13) Å]. The four-coordinate Ag atom has a seesaw coordination geometry with a τ_4 index of 0.51. The tetrafluoridoborate anion is disordered over two orientations with 0.568 (10):0.432 (10) occupancies.

Related literature

Bis(2-acetylpyridine- κ^2N,O)silver(I) tetrafluoridoborate: a complex with silver in a seesaw coordination geometry

Michael A. O'Donnell and Peter J. Steel

S1. Comment

For some time we have been involved in the study of silver complexes of chelating and bridging heterocyclic ligands (Steel, 2005; Fitchett & Steel, 2006; O'Keefe & Steel, 2007; Steel & Fitchett, 2008; Golder *et al.*, 2010). 2-acetylpyridine coordinates to a variety of transition metals, usually as an N,O-chelating ligand, although it has been reported to act as an O-monodentate donor to a zinc porphyrin (Byrn *et al.*, 1993). X-ray crystal structures have been reported for complexes of 2-acetylpyridine with silver(I) perchlorate (Bowmaker *et al.*, 2005; Drew *et al.*, 2005), trifluoroacetate (Bowmaker *et al.*, 2005), trifluoromethanesulfonate (Di Nicola *et al.*, 2010) and nitrate (Bowmaker *et al.*, 2005). The latter has a single 2-acetylpyridine bound to the silver with a chelating nitrate anion, while the others have two chelating 2-acetylpyridine ligands. We now report the structure of its complex with silver(I) tetrafluoridoborate, the title compound $[\text{Ag}(\text{C}_7\text{H}_7\text{NO})_2]\text{BF}_4$ (I).

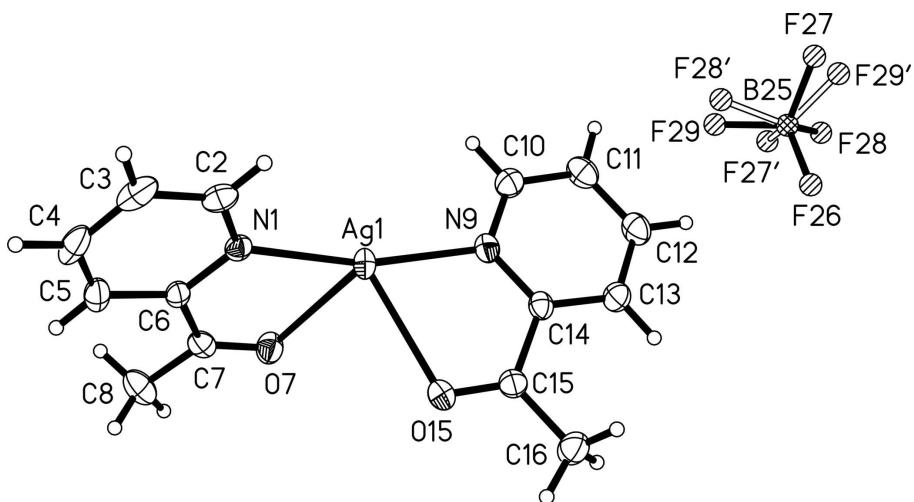

In (I), the asymmetric unit contains a complex cation comprising a silver(I) atom bound to two bidentate N,O-chelated 2-acetylpyridine ligands [$\text{Ag}-\text{N}$, 2.2018 (15), 2.2088 (14) Å; $\text{Ag}-\text{O}$, 2.5380 (13), 2.5454 (13) Å], and a tetrafluoridoborate counter-anion (Fig. 1). The tetrafluoridoborate anion is disordered over two orientations with relative F occupancies of 57:43% about a common central B. Since the silver atom makes no other contacts less than 2.72 Å it should be classified as four-coordinate (Young & Hanton, 2008). Calculation of the τ_4 index (Yang *et al.*, 2007) produces a value of 0.51 which means that the geometry around the silver should be described as seesaw.

S2. Experimental

The title compound was prepared by diffusion of pentane into a methanol solution of a mixture of 2-acetylpyridine and silver(I) tetrafluoridoborate.

S3. Refinement

Hydrogen atoms were included in calculated positions as riding atoms, with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ for the pyridine H atoms and $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ for the acetyl H atoms. The occupancies for the disordered F atoms of the BF_4^- anion were 0.568 (10)/0.432 (10) and were fixed at 0.57/0.43 in the refinement.

**Figure 1**

The molecular structure of the title complex, showing displacement ellipsoids at the 50% probability level.

$$\Delta\rho_{\min} = -0.47 \text{ e } \text{\AA}^{-3}$$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
