Received 21 November 2010; accepted 29 November 2010

Key indicators: single-crystal X-ray study; $T = 294\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.019\text{ \AA}$; R factor = 0.060; wR factor = 0.161; data-to-parameter ratio = 11.7.

In the title complex, $[\text{BaCd}(\text{C}_3\text{H}_2\text{O}_4)_2(\text{H}_2\text{O})_4]_n$, the Ba^{II} atoms, located on crystallographic twofold axes, adopt slightly distorted square-antiprismatic coordination geometries, while the Cd^{II} atoms, which lie on crystallographic centres of symmetry, have a distorted octahedral coordination. Each malonate dianion binds two different Cd^{II} atoms and two different Ba^{II} atoms. This connectivity generates alternating layers along [100] in the structure, with one type containing Cd^{II} cations and malonate dianions, while the other is primarily composed of Ba^{II} ions and coordinated water molecules. The water molecules also participate in extensive $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonding.

Poly[tetraqua-di- μ_4 -malonato-barium(II)cadmium(II)]

Ming-Lin Guo, Wen-Jun Gao, Cong-Cong Luo and Long Liu

S1. Comment

The malonate dianion, with two neighboring carboxylate groups, is a very flexible ligand. Its basic coordination mode is as a chelate *via* two distal carboxylate oxygen atoms to form a six-membered ring and the coordinating ability of the nonchelating oxygen atoms makes the formation of polymeric networks possible (Djeghri *et al.*, 2005; Guo & Guo, 2006). On the other hand, malonate can also coordinate in monodentate, chelated bidentate and bridging modes to create various molecular architectures (Delgado *et al.*, 2004). Herein, we report the structure of the title heterobimetallic malonate complex, (I). It and the chemically similar complex poly[tetraqua-di-mu4-malonato-barium(II)zinc(II)] (Guo & Guo, 2006) are isotypic.

The asymmetric unit in the structure of (I) comprises half a Ba^{II} cation, half a Cd^{II} cation, a complete malonate dianion defined by C1—C3/O1—O4 and two independent water molecules involving O5 and O6. Fig. 1 shows a symmetry-expanded view which displays the full coordination of the Ba²⁺ and Cd²⁺ centers. Selected geometric parameters are given in Table 1.

The Ba²⁺ cation, lying on a crystallographic twofold axis, is eight-coordinate, bonded to oxygen atoms of four different malonate groups and four water molecules with Ba—O distances ranging from 2.793 (9) to 2.878 (10) Å. The Ba polyhedra may be described as slightly distorted square antiprisms. They share edges to form chains propagating along *c*.

The Cd²⁺ cations, lie on crystallographic centres of symmetry, and have distorted octahedral coordination, with O2 and O3 of two bidentate malonate anions at the equatorial sites and two O1 atoms from two other malonate anions at the apical sites.

Also evident in Fig. 1 is the variability of the coordination modes of the malonate dianion with monodentate (O1), bidentate chelating (O2 and O3) and bridging (O4) bonding modes all present.

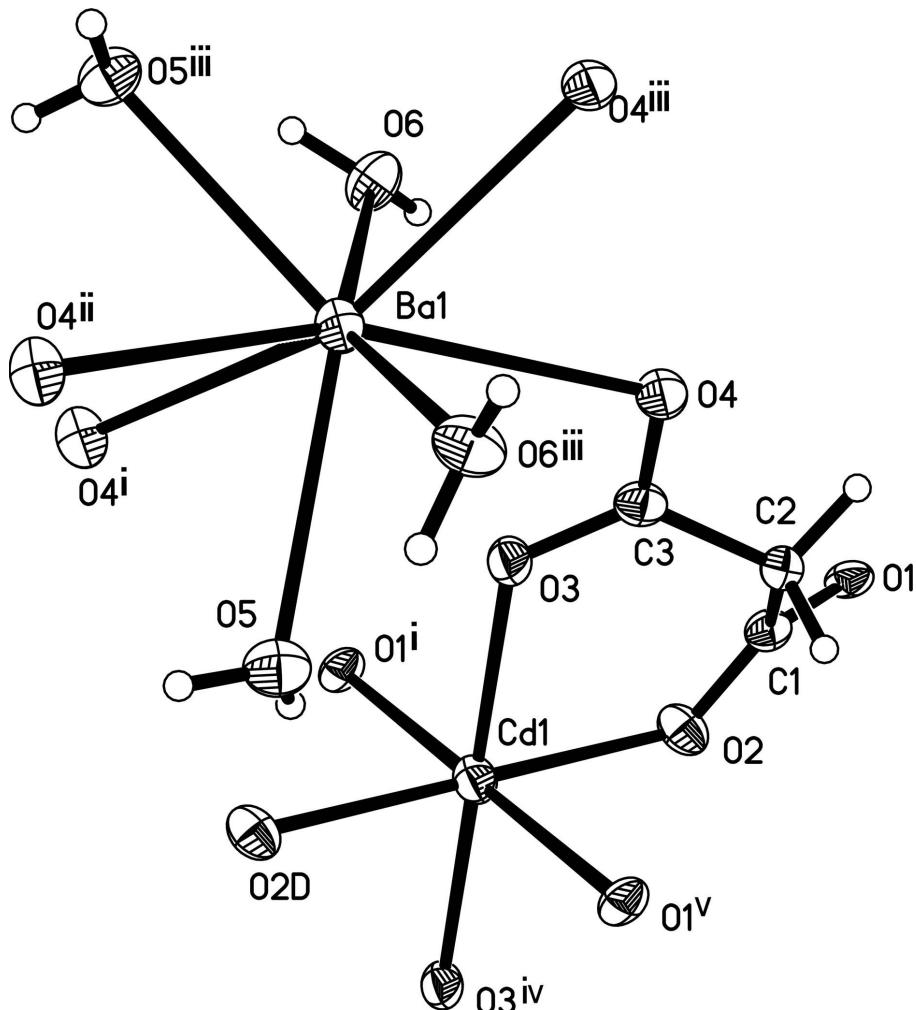

The structure as a whole consists of two distinct types of layer, both parallel to (100) and stacked alternately in the direction of *a*. The first of these (Fig. 2) is composed entirely of Cd^{II} ions and malonate dianions and occurs at *x* = 0 and 1/2. The other type of layer, type 2, alternating with the first and centred on *x* = 1/4 and 3/4 contains, primarily, the Ba ions and the water molecules. Two forms of connectivity occur within the type 2 layers. First of all O4 atoms on the surfaces of the type 1 layers create chains of edge sharing Ba polyhedra propagating along *c* and at the same time link the two types of layer and complete the three-dimensional connectivity of the structure. The interlayer connectivity is further enhanced by the hydrogen bonds of the form O5—H5A···O2^{iv} and O6—H6A···O1^{vi} given in Table 2.

S2. Experimental

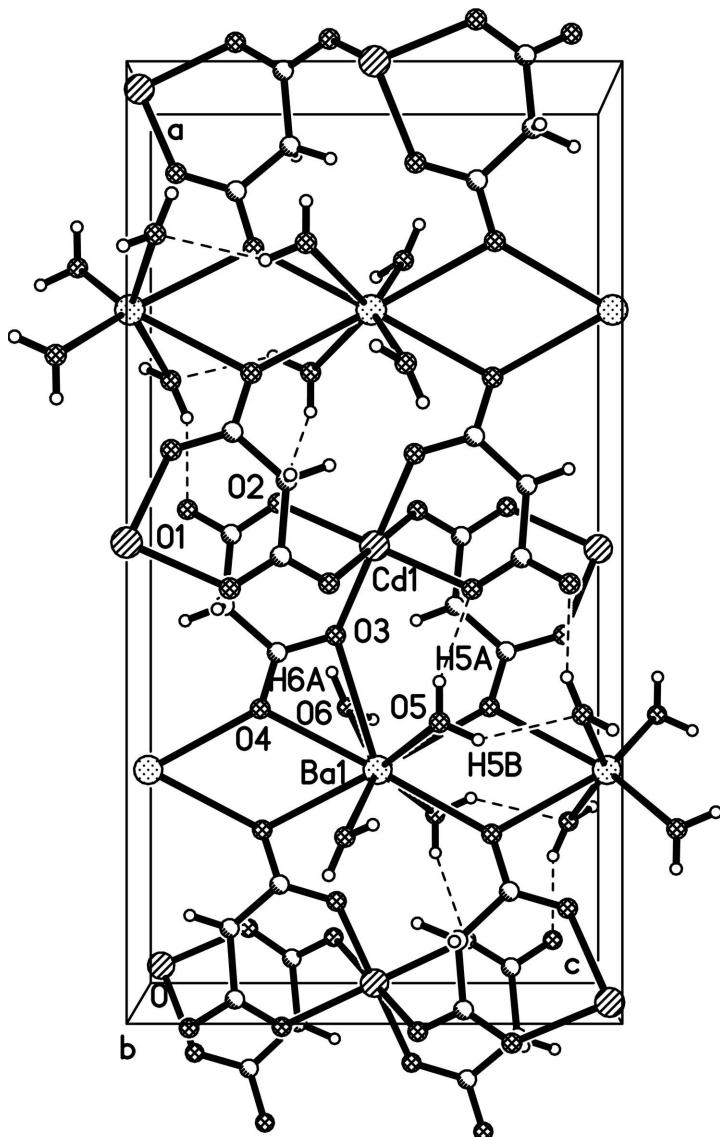

The title complex was prepared under continuous stirring with successive addition of malonic acid (0.43 g, 4 mmol), cadmium(II) chloride (0.37 g, 2 mmol) and Ba(OH)₂·8H₂O (0.63 g, 2 mmol) to distilled water (40 ml) at room temperature. After filtration, slow evaporation over a period of a week at room temperature provided colorless plate-like crystals of (I).

S3. Refinement

The H atoms of the water molecule were found in difference Fourier maps and during refinement were fixed at an O–H distance of 0.85 Å, and with $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{O})$. The H atoms of C–H groups were placed geometrically and during refinement were treated using a riding model, with C–H = 0.97 Å, and with $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$.

**Figure 1**

The coordination of the metal ions in (I). Displacement ellipsoids are drawn at the 30% probability level. Symmetry codes (i) $x, -y + 1/2, z + 1/2$; (ii) $-x + 1/2, y, z + 1/2$; (iii) $-x + 1/2, -y + 1/2, z$; (iv) $-x + 1, -y + 1, -z + 1$; (v) $-x + 1, y + 1/2, -z + 1/2$.

**Figure 2**

A view, approximately along the *b* axis, showing the alternation of type 1 and type 2 layers along the *a* axis.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
