Received 31 December 2010; accepted 17 January 2011

Key indicators: single-crystal X-ray study; $T=299 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.006 \AA$; $R$ factor $=0.032 ; w R$ factor $=0.051$; data-to-parameter ratio $=13.6$.

Trisilver(I) citrate, $3 \mathrm{Ag}^{+} \cdot \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}{ }^{3-}$, was obtained by evaporation of a saturated aqueous solution of the raw material that had been obtained from sodium dihydrogen citrate and silver nitrate. It features one formula unit in the asymmetric unit. There is an intramolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond between the OH group and one of the terminal carboxylate groups. Different citrate groups are linked via the three $\mathrm{Ag}^{+}$ ions, yielding a three-dimensional network with rather irregular $\left[\mathrm{AgO}_{4}\right]$ polyhedra.

## Trisilver(I) citrate

## Andreas Fischer

## S1. Comment

The structures of many citrates of common metal ions are surprisingly sparsely investigated. Of the citrates of coinage metal cations, only ammonium disilver citrate monohydrate (Sagatys et al., 1993) and tetraammonium copper(II) bis(citrate) (Bott et al. 1991) have been reported. Here, we report the crystal structure of trisilver citrate, which was obtained from mixing solutions of sodium dihydrogen citrate and silver nitrate.

The basic structural of the 3D-polymeric structure shows an intramolecular hydrogen bond $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ bond between O 5 and O7 (Fig. 1). As expected from the charges, all three carboxy groups are deprotonated. The coordination polyhedra about the $\mathrm{Ag}^{+}$cations are quite irregular, the $\mathrm{Ag}-\mathrm{O}$ distances are in the range 2.275 (3) to 2.566 (3) $\AA$ (Table 1). The $\mathrm{Ag} 2-$ Ag 3 contact of 2.8801 (6) $\AA$ is the shortest one in the structure. It can be noted that significantly shorter distances $\mathrm{Ag}^{+}-$ $\mathrm{Ag}^{+}$are observed in many silver coordination compounds.

## S2. Experimental

An aqueous solution ( $0.5 \mathrm{~mol} / \mathrm{L}$ ) of sodium dihydrogen citrate was prepared by dissolving the respecitve amounts of trisodium citrate (Merck, p.a.) and citric acid in demineralised water. 1 mL of this solution was added to 1 mL of a solution of silver nitrate $(0.5 \mathrm{~mol} / \mathrm{L})$, yielding a white precipitate. The latter was washed with demineralised water. The precipitate was then heated to 323 K with 1 mL of demineralised water. Upon cooling to room remperature, the saturated solution was filtered off and put aside for evaporation. Within a couple of days, small, colourless, rod-like crystals formed, that were suitable for structure determination. It can be noted that crystals of the title compound turned brown during the structure determination; however, no significant decrease in diffraction intensity could be observed. The initial precipitate formed from sodium dihydrogen citrate and silver nitrate was investigated by powder diffraction and it could be confirmed that it consisted of pure trisilver citrate. In addition, this powder pattern is identical with that of commercial "silver citrate hydrate".

## S3. Refinement

Methylene-H atoms were placed at calculated positions ( $\mathrm{C}-\mathrm{H}=0.97 \AA, U_{i s o}=1.2 U_{e q}$ of the respective C atom). The hy-droxy-H atom was located from the Fourier map and was refined with a restraint $(\mathrm{O}-\mathrm{H}=0.82(2) \AA)$ and $\left.U_{\text {iso }}=1.5 U_{e q}(\mathrm{O})\right)$. The largest Fourier peak/hole ( 1.21 and $-1.21 \mathrm{e} / \AA^{3}$, respectively), are found 0.82 and $0.77 \AA$ from Ag 2 .

\((\Delta / \sigma)_{\text {max }}=0.001\)
```

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
