Received 3 December 2010; accepted 10 January 2011

Key indicators: single-crystal X-ray study; $T = 173\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; R factor = 0.033; wR factor = 0.084; data-to-parameter ratio = 9.9.

The title compound, $\text{C}_9\text{H}_{18}\text{NO}_2^+\cdot\text{NO}_3^-$, is an anhydrous nitrate salt of gabapentin, which is formed serendipitously in the presence of selected non-coordinating metals. The crystal structure involves extensive hydrogen bonding between the $-\text{NH}_3^+$ and $-\text{COOH}$ groups and the nitrate anion.

Related literature

For related structures, see: Ibers (2001); Ananda *et al.* (2003); Reece & Levendis (2008); Braga *et al.* (2008); Fabbiani *et al.* (2010). For the role of γ -aminobutyric acid (GABA) as an inhibitory neurotransmitter, see: Bowery (1993). Gabapentin is used as a neuroleptic drug in the treatment of epilepsy (Taylor, 1993) but its applications have been extended to the treatment of neuropathic pain (Magnus, 1999).

[1-(Carboxymethyl)cyclohexyl]methanaminium nitrate

Elise J. C. de Vries, Caryn Gamble and Ahmed Shaikjee

S1. Comment

The role of γ -aminobutyric acid (GABA) as an inhibitory neurotransmitter (Bowery, 1993) has stimulated research on the synthesis of GABA analogues as potential central nervous system agents. One of these analogues is the amino acid gabapentin [1-(aminomethyl)cyclohexaneacetic acid] which is commercially available as Neurotin. Gabapentin is used as a neuroleptic drug in the treatment of epilepsy (Taylor, 1993) but its applications have been extended to the treatment of neuropathic pain (Magnus, 1999). Gabapentin is widely studied and already four polymorphic forms of the drug are known, three polymorphic forms under ambient conditions (Ibers, 2001; Reece and Levendis, 2008; Braga *et al.*, 2008) and a fourth at high pressure (Fabbiani *et al.*, 2010). The present paper reports on the formation of an anhydrous gabapentin nitrate salt, complex (I).

Complex (I) was obtained serendipitously when investigating the possibility of producing novel metal complexes with gabapentin. Lithium-, chromium-, indium-, iron- and aluminium nitrate were used in an attempt to make metal complexes. However analysis of the crystalline materials revealed a gabapentin nitrate salt was obtained in each case. The atomic numbering scheme of the gabapentin nitrate complex, $C_9H_{18}NO_2^+ \cdot NO_3^-$, is shown in Fig. 1. Complex (I) crystallizes in the orthorhombic space group $P2_12_12_1$ with a protonated amine group. The cyclohexane ring is in the chair conformation with the ammonium group in the equatorial position. The conformation of the gabapentin molecule is defined by the formation of an intramolecular hydrogen bond between the carboxylate oxygen and one of the hydrogen atoms belonging to the ammonium group ($N1—H1C\cdots O1$). The crystal packing shows how each nitrate anion links to three adjacent molecules by means of one $O—H\cdots O$, four $N—H\cdots O$, two $N—H\cdots N$ and one $O—H\cdots N$ hydrogen-bonding interactions. The donors are the H atoms of the carboxylic acid and amine group, while the acceptors include all three O atoms of the nitrate anion (Fig. 2). Additionally, one nitrate O atom is involved in a weak hydrogen bonding interaction with a symmetry related carbon atom, with a $C9—H9B\cdots O3$ distance of 3.317 (3) Å and angle of 149°.

S2. Experimental

Gabapentin was purchased from Sigma-Aldrich. The gabapentin nitrate salt is formed serendipitously by combining gabapentin with one of the following metal salts in 1:1 stoichiometric ratios; lithium-, chromium-, indium-, iron- and aluminium nitrate. The metal salt and gabapentin were dissolved in 0.1 molar nitric acid and allowed to undergo slow evaporation at ambient temperature. It was noted that this complex did not form if the metal salt was removed from the reaction.

S3. Refinement

All H atoms were positioned geometrically and allowed to ride on their respective parent atoms, with C—H bond lengths of 0.99 (aromatic CH) 1.00 (methine CH), 0.99 (methylene CH_2) and 0.98 Å (methyl CH_3), and with $U_{iso}(H) = 1.2$ or 1.5 times $U_{eq}(C)$. In the absence of significant anomalous scattering, Friedel equivalents were merged before the final

refinement.

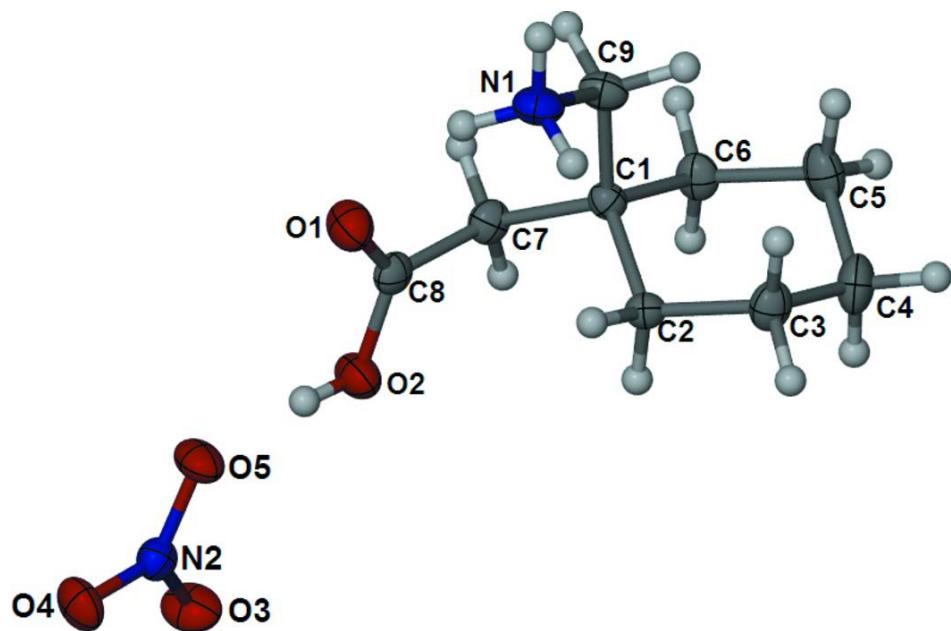

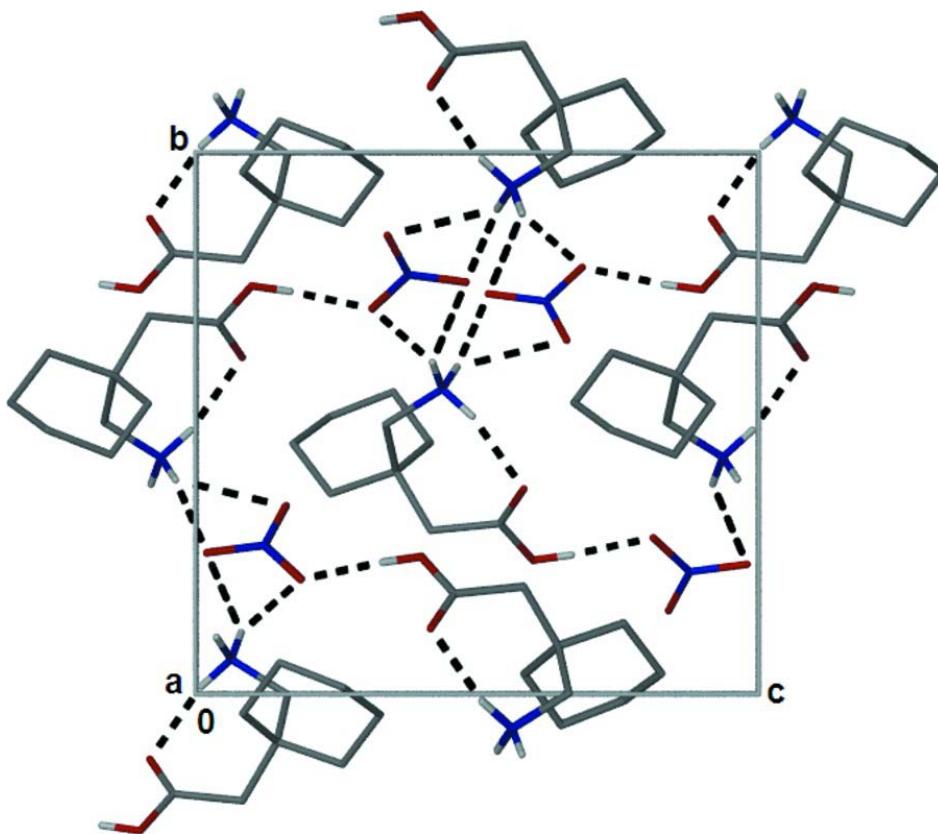

Figure 1

The atomic numbering scheme of complex (I). Displacement ellipsoids are drawn at 50% probability level.

**Figure 2**

Projection of the unit cell of complex (I) down the a axis. All hydrogen atoms removed, except those involved in hydrogen bonding. Hydrogen bonds are indicated as dashed lines.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
