Redetermination of synthetic warwickite, $Mg_3TiO_2(BO_3)_2$

Tetsuya Kawano and Hisanori Yamane*

Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, 2-1-1 Katahira, Aoba-ku, Sendai, 980-8577, Japan Correspondence e-mail: yamane@tagen.tohoku.ac.jp

Received 22 December 2010; accepted 14 January 2011

Key indicators: single-crystal X-ray study; T = 293 K; mean σ (O–B) = 0.003 Å; disorder in main residue; R factor = 0.026; wR factor = 0.070; data-to-parameter ratio = 8.3.

Single crystals of warwickite, trimagnesium titanium(IV) dioxide bis(borate), Mg₃TiO₂(BO₃)₂, were prepared by slow cooling of the melt. The title compound is isotypic with $Co_3TiO_2(BO_3)_2$. In contrast to the previous refinement of warwickite [Moore & Araki (1974). Am. Mineral. 59, 985-1004], that reported only isotropic atomic displacement parameters for all atoms, anisotropic displacement parameters of all atoms were refined during the current redetermination. All atoms are situated on special positions (site symmetry.m.). One of the two Mg sites is statistically disordered with Ti atoms (ratio 1:1), while the other is fully occupied by Mg atoms. The occupancy ratio of the Mg and Ti atoms is similar to that reported in the previous study. Metal atoms (M) at the Ti/Mg and Mg sites are coordinated by six O atoms in form of distorted octahedra. Four edge-sharing MO₆ octahedra form M_4O_{18} units, which are connected by common corners into layers parallel to (010). Adjacent layers are linked along [010] into a framework structure by sharing common edges. The B atoms are located in the triangular prismatic tunnels of the framework.

Redetermination of synthetic warwickite, Mg₃TiO₂(BO₃)₂

Tetsuya Kawano and Hisanori Yamane

S1. Comment

Crystal structure determinations of the mineral warwickite, Mg₃TiO₂(BO₃)₂, were reported by Takéuchi *et al.* (1950) and Moore & Araki (1974). The natural samples contained a few amount of Fe and Al. The crystal structure of synthetic Mg₃TiO₂(BO₃)₂ has not been analyzed up to now. We obtained single crystals of this compound during the preparation of Mg₅TiO₄(BO₃)₂ (Kawano & Yamane, 2010). Anisotropic atomic displacement parameters (U_{ij}) of Mg, Ti, B and O atoms were refined in the present study. Moore & Araki (1974) refined isotropic atomic displacement parameters (B_{iso}) of Mg, Ti, B and O atoms; neither *U* nor *B*-values were reported by Takéuchi *et al.* (1950).

Synthetic warwickite-type oxyborates with general composition $M^{II}_{3}M^{IV}O_2(BO_3)_2$ are known for $Co_3MO_2(BO_3)_2$ [M = Ti, Zr (Utzolino & Bluhm, 1995)] and Mg₃ZrO₂(BO₃)₂ (Konijnendijk & Blasse, 1985). However, only the crystal structures of $Co_3MO_2(BO_3)_2$ (M = Ti, Zr) were analyzed. The title compound Mg₃TiO₂(BO₃)₂ is isotypic with $Co_3MO_2(BO_3)_2$ [M = Ti, Zr (Utzolino & Bluhm, 1995)].

Figs. 1 and 2 show the coordination environments of the Mg, Ti, B and O atoms, and the crystal structure of Mg₃TiO₂(BO₃)₂, respectively. In the asymmetric unit, there is one Ti/Mg mixed site (*M*1) with occupancies of 0.5/0.5 and one Mg site (*M*2). Moore and Araki (1974) refined the site occupancy factors of Mg and Ti atoms at the *M*1 and *M*2 sites, ignoring Al and Fe atoms due to their similarities with the scattering profiles of Mg²⁺ and Ti⁴⁺, respectively. Refined occupancy factors were $M1 = Mg_{0.96(1)}/Ti_{0.04(1)}$ and $M2 = Mg_{0.62(2)}/Ti_{0.38(2)}$ and an ideal formula of Mg(Mg_{0.5}Ti_{0.5})O₂[BO₃] was suggested (Moore & Araki, 1974). Our refinement (M1 = Mg1 and $M2 = Mg_{0.5}/Ti_{0.5}$) is consistent with the ideal formula. Although Takéuchi *et al.* (1950) reported the atomic coordinates of natural warwickite, site occupancy factors of the *M*1 and *M*2 sites were not reported.

All atoms are at special positions (x, 1/4, z), 4c, with site symmetries of (.m.). Mg and Ti atoms occupy six-coordinated oxygen-octahedral sites, forming layers composed of M_4O_{18} (M = Ti/Mg, Mg) units. The layers are connected by edge-sharing O4 atoms of (Ti1/Mg1)O₆ and Mg2O₆ octahedra into a three-dimensional framework. B1 atoms are located in triangular prismatic tunnels of the framework.

Bond valence sums (BVS; Brown & Altermatt, 1985) of the Mg, Ti and B atoms were calculated with the bond valence parameters of 1.693 Å for Mg^{2+} , 1.815 Å for Ti^{4+} and 1.371 Å for B^{3+} (Brese & O'Keeffe, 1991). The BVS values of the Mg2 and B1 atoms were 2.1 and 2.9, respectively. Those of the Ti1 and Mg1 atoms at the Ti1/Mg1 site were 3.22 and 2.31, respectively. The average of these value is 2.8 and close to the expected mean valence (+3) of Mg²⁺ and Ti⁴⁺. The B1—O distances of 1.353 (3)–1.395 (3) Å agree well with those of isotypic $Co_3MO_2(BO_3)_2$ (M = Ti, Zr): 1.36 (2)–1.39 (2) Å (Utzolino & Bluhm, 1995).

Warwickite-type $Mg_3TiO_2(BO_3)_2$ did not emit visible light under ultraviolet excitation at room temperature, while ludwigite-type $Mg_5TiO_4(BO_3)_2$ shows broad blue emission (435 nm) attributed to charge transfer transitions between Ti⁴⁺ and O²⁻ (Konijnendijk & Blasse, 1985).

S2. Experimental

Starting materials were powders of MgO (99.9%, Rare Metallic), TiO₂ (99.9%, Rare Metallic) and H₃BO₃ (99.99%, Sigma-Aldrich). MgO was heated at 1173–1273 K for 6–12 h in air before weighing. The powders were weighed with a molar ratio of MgO: TiO₂: H₃BO₃ = 5: 1: 2.7 and mixed in an agate mortar with a pestle. The mixture was pressed into a pellet, placed in a Pt boat and heated at 1623 K for 6 h in air. Heating and cooling rates were 200 and 900 K/h, respectively. About 400 mg of the sample and 100 mg of H₃BO₃ were weighed and mixed. The mixture in the Pt boat was heated at 1723 K for 3 h in air and cooled to room temperature at a cooling rate of 900 K/h. The obtained sample was crushed into fragments and a colourless and transparent single-crystal of about 0.12–0.17 mm was picked up under an optical microscope.

S3. Refinement

The crystal structures of natural warwickites were described in the space group *Pnam* (no. 62) in the previous studies (Takéuchi *et al.*, 1950; Moore & Araki, 1974). The original single-crystal X-ray diffraction data in the present study were indexed in a different setting in space group *Pmnb* and unit-cell parameters of a = 3.10080 (14), b = 9.3013 (5) and c = 9.3914 (6) Å. Structure parameters were eventually standardized based on the standard setting of the space group *Pnma* using the *STRUCTURE TIDY* program (Gelato & Parthé, 1987). In the final refinement, site occupation factors (s.o.f.'s) of the Ti and Mg atoms at the Ti1/Mg1 and Mg2 sites were fixed to 0.5/0.5 and 1.0, respectively, since the freely refined s.o.f.'s of the Ti and Mg atoms at the Ti1/Mg1 site were close to 1/2, and the s.o.f. of the Mg atom at the Mg2 site was about 1.0. The highest peak in the difference electron density map is 0.36 Å from O2 while the deepest hole is -0.59 Å from Ti1/Mg1.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted *R*-factor *wR* and goodness of fit *S* are based on F^2 , conventional *R*-factors *R* are based on *F*, with *F* set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating *R*-factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. *R*-factors based on F^2 are statistically about twice as large as those based on *F*, and *R*- factors based on ALL data will be even larger.
