Received 12 December 2010; accepted 26 January 2011

Key indicators: single-crystal X-ray study;  $T = 293\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.007\text{ \AA}$ ; H-atom completeness 86%;  $R$  factor = 0.046;  $wR$  factor = 0.127; data-to-parameter ratio = 14.0.

The crystal structure of the title compound,  $[\text{Ni}_6(\text{C}_{13}\text{H}_{10}\text{NO}_2)_4(\text{N}_3)_8(\text{CH}_3\text{OH})_8] \cdot 6\text{CH}_3\text{OH}$ , consists of a centrosymmetric hexanuclear  $[\text{Ni}^{II}]_6(\text{C}_{13}\text{H}_{10}\text{NO}_2)_4(\text{N}_3)_8(\text{CH}_3\text{OH})_8$  molecule and six methanol solvent molecules. In the hexanuclear unit, the six octahedrally coordinated  $\text{Ni}^{II}$  atoms are linked by four  $\mu_{1,1,1}$ -azide and four  $\mu_{1,1}$ -azide bridges, forming a face-sharing  $\text{Ni}_6\text{N}_8$  tetracubane-like unit with four missing corners. The  $\text{Ni}^{II}$  atoms are further bridged by four  $\mu_{1,2}$ -carboxalate groups. Neighbouring hexanuclear units are connected via  $\text{N}-\text{H}\cdots\text{O}$  hydrogen-bonding interactions into a three-dimensional structure. Although the H atoms of the methanol OH groups could not be located,  $\text{O}\cdots\text{N}/\text{O}$  contacts between 2.65 and 2.86 Å suggest that these molecules participate in hydrogen bonding.

### S1. Comment

The design and synthesis of new polynuclear metal complexes for single molecule magnets have attracted great interest in coordination chemistry, because single molecule magnets not only show fascinating physical properties, but also have potential application in information storage and quantum computing at the molecular level (Liu *et al.*, 2008). To date, although it is difficult to predict which kind of topology and structure will lead to high-nuclearity compounds in advance, many synthetic approaches have been employed to obtain well-isolated polynuclear complexes, e.g. by using new blocking ligands with short bridges. Many single molecule magnets are based on Mn<sup>III</sup>, Fe<sup>III</sup>, and Ni<sup>II</sup>. In most of these compounds, magnetic exchange interactions are mainly propagated by bridging OH<sup>-</sup>, OR<sup>-</sup>, O<sup>2-</sup>, or RCO<sup>2-</sup> groups, which often transmit antiferromagnetic interactions. An attractive strategy to facilitate the formation of ferromagnetic coupled clusters is to utilize azide and carboxalate-containing ligands simultaneously (Liu *et al.*, 2006). Herein, we report the synthesis and structure of the hexanuclear Ni(II) complex, [Ni<sub>6</sub>(C<sub>13</sub>H<sub>10</sub>NO<sub>2</sub>)<sub>4</sub>(N<sub>3</sub>)<sub>8</sub>(CH<sub>3</sub>OH)<sub>8</sub>]·6CH<sub>3</sub>OH.

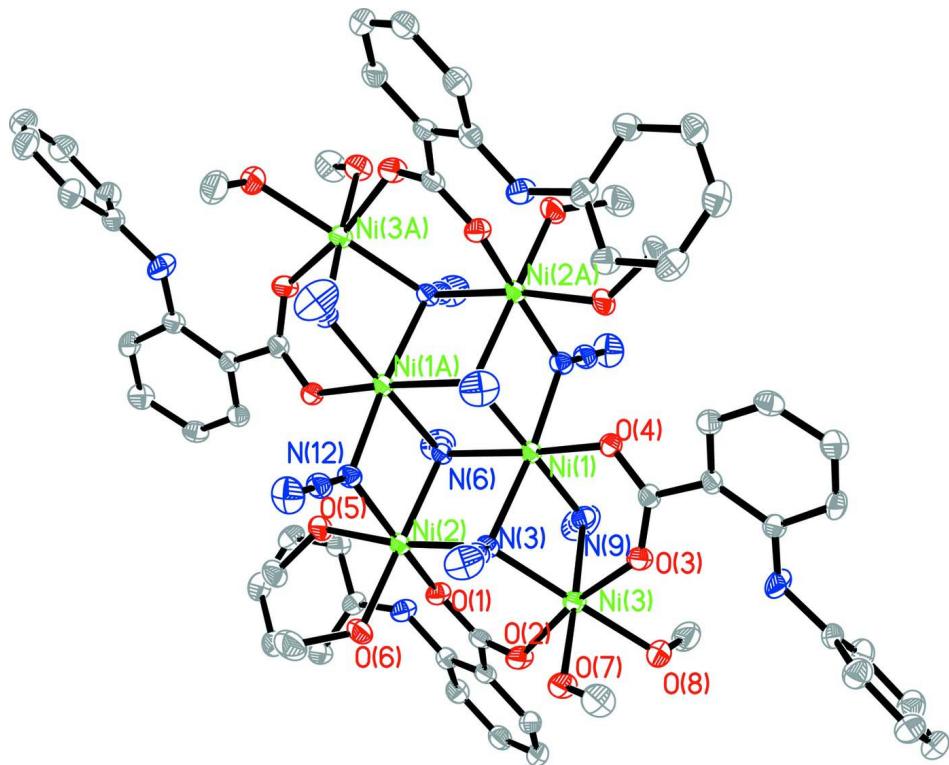

The structure of the title compound consists of neutral hexanuclear [Ni<sup>II</sup><sub>6</sub>(C<sub>13</sub>H<sub>10</sub>NO<sub>2</sub>)<sub>4</sub>(N<sub>3</sub>)<sub>8</sub>(CH<sub>3</sub>OH)<sub>8</sub>] molecules and six methanol solvate molecules situated between the hexanuclear units. The complete molecule has inversion symmetry. In the neutral hexanuclear unit, six octahedrally coordinated Ni<sup>II</sup> atoms are linked by four  $\mu_{1,1,1}$ -azido and four  $\mu_{1,1}$ -azido bridges, forming face-sharing tetracubane units with four missing corners based on the Ni<sub>6</sub>N<sub>8</sub> core. The Ni<sup>II</sup> atoms are further bridged by four  $\mu_{1,2}$ -carboxalate ligands (Fig. 1). The Ni—O distances range between 2.000 (3)–2.094 (3) Å, and the Ni—N distances between 2.052 (4)–2.165 (3) Å. These bond lengths indicate that the Ni<sup>II</sup> ions are in the divalent state, and are in agreement with other Ni<sup>II</sup> complexes (Wang *et al.*, 2008). The hexanuclear units are connected *via* N—H···O hydrogen bonding into a three-dimensional structure (Fig. 2). The N—H···O hydrogen bonding (Table 2) is accomplished through the N atoms of 2-phenylamino-benzoate and O atoms of carboxylate groups, with the N···O distances being 2.667–2.676 Å. Although the H atoms of the methanol OH groups could not be located, short O···N/O contacts suggest that these molecules participate in hydrogen bonding between O atoms of methanol as donors and acceptors, and between O atoms of methanol and N atoms of azido bridges, with O···O distances in the range of 2.65–2.72 Å, and O···N distances in the range of 2.79–2.86 Å.

### S2. Experimental

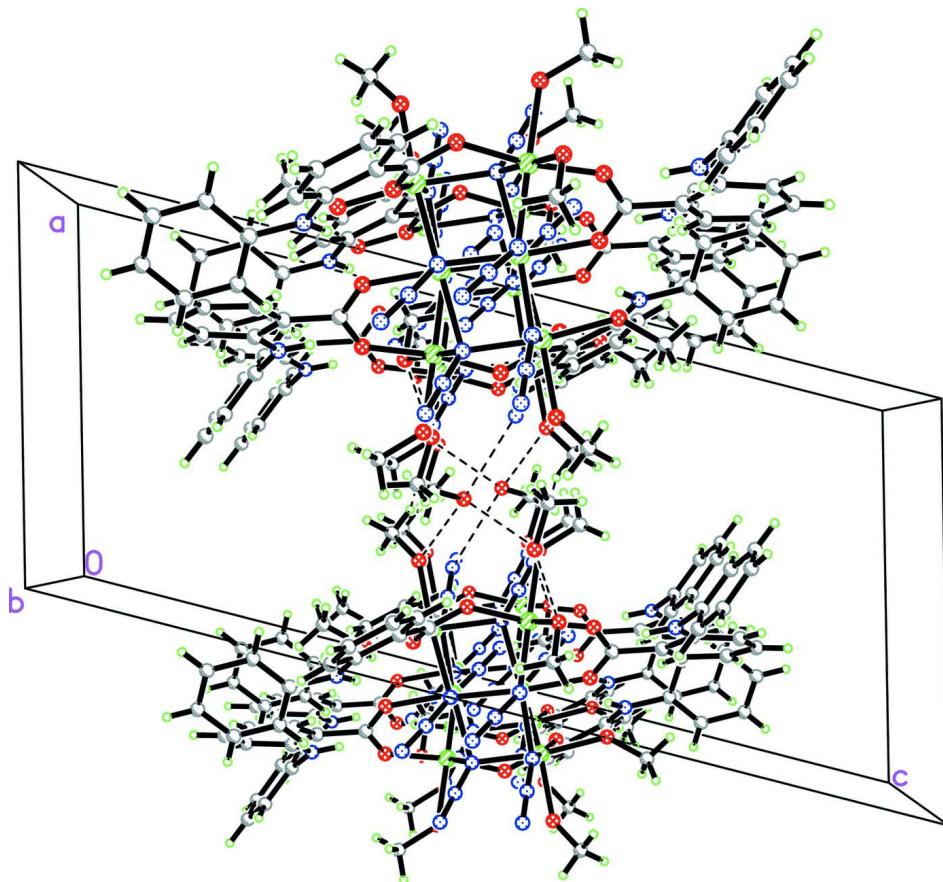

Under stirring, 2.0 mmol 2-phenylamino-benzoic acid, 4.0 mmol NaN<sub>3</sub> were added, one after another, into a 20 ml methanol solution containing 1.0 mol Ni(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O. The resulting solution was kept stirred for another hour, and then filtered off. The filtered solution was allowed to stand undisturbed in a sealed vessel. Crystallization took one week and gave block-shaped green crystals in a yield of 40% based on Ni(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O. The product was washed with methanol and dried in air.

**S3. Refinement**

Hydrogen atoms bonded to C and N atoms were added geometrically and were refined using a riding model, with C—H = 0.96 Å (CH<sub>3</sub>), C—H = 0.93 Å (C—H) and N—H = 0.86 Å. The hydrogen atoms of the OH group of the methanol molecules could not be derived from Fourier maps and were eventually not included in the refinement.

**Figure 1**

The hexanuclear unit of the title structure. The non-C atoms are labelled; all atoms are shown with displacement ellipsoids at the 30% probability level. H atoms have been omitted for clarity.

**Figure 2**

A view of the crystal packing along the *b* axis. Hydrogen bonding is indicated with dashed lines.

### Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
