

Redetermination of  $\text{AgPO}_3$ Katherina V. Terebilenko,<sup>a\*</sup> Igor V. Zatovsky,<sup>a</sup> Ivan V. Ogorodnyk,<sup>a</sup> Vyacheslav N. Baumer<sup>b</sup> and Nikolay S. Slobodyanik<sup>a</sup><sup>a</sup>Department of Inorganic Chemistry, Taras Shevchenko National University, 64 Volodymyrska Street, 01601 Kyiv, Ukraine, and <sup>b</sup>STC 'Institute for Single Crystals', NAS of Ukraine, 60 Lenin Avenue, 61001 Kharkiv, Ukraine  
Correspondence e-mail: tereb@bigmir.ru

Received 19 January 2011; accepted 31 January 2011

Key indicators: single-crystal X-ray study;  $T = 293$  K; mean  $\sigma(\text{P}-\text{O}) = 0.002$  Å;  $R$  factor = 0.024;  $wR$  factor = 0.058; data-to-parameter ratio = 25.4.

Single crystals of silver(I) polyphosphate(V),  $\text{AgPO}_3$ , were prepared *via* a phosphoric acid melt method using a solution of  $\text{Ag}_3\text{PO}_4$  in  $\text{H}_3\text{PO}_4$ . In comparison with the previous study based on single-crystal Weissenberg photographs [Jost (1961). *Acta Cryst.* **14**, 779–784], the results were mainly confirmed, but with much higher precision and with all displacement parameters refined anisotropically. The structure is built up from two types of distorted edge- and corner-sharing [ $\text{AgO}_5$ ] polyhedra, giving rise to multidirectional ribbons, and from two types of  $\text{PO}_4$  tetrahedra linked into meandering chains ( $\text{PO}_3$ )<sub>*n*</sub> spreading parallel to the *b* axis with a repeat unit of four tetrahedra. The calculated bond-valence sum value of one of the two  $\text{Ag}^{\text{I}}$  ions indicates a significant strain of the structure.

## Related literature

## Redetermination of $\text{AgPO}_3$

Katherina V. Terebilenko, Igor V. Zatovsky, Ivan V. Ogorodnyk, Vyacheslav N. Baumer and Nikolay S. Slobodyanik

### S1. Comment

Glassy silver polyphosphates as a part of complex oxide-chalcogenide systems have various applications in the field of solid electrolytes (Portier *et al.*, 1990; Novita *et al.*, 2009). Much attention has therefore been paid to phase equilibrium studies within  $\text{AgPO}_3\text{-}M(\text{PO}_3)_n$  systems, where  $M$  is a rare earth (Ayadi *et al.*, 2009; Naili *et al.*, 2006; El Masloumi *et al.*, 2005), a divalent (Belharouak *et al.*, 1999) or a monovalent metal (Averbuch-Pouchot, 1993).

The title compound is isotopic with the  $A$ -form of the Kurrol salt  $\text{NaPO}_3$  (McAdam *et al.*, 1968).  $\text{AgPO}_3$  has been previously structurally studied based on single crystal Weissenberg photographs (Jost, 1961). The current study mainly confirms the previous results, but with significantly higher precision and with anisotropic displacement parameters refined for all atoms.

The structure of  $\text{AgPO}_3$  features two types of penta-coordinated  $\text{Ag}^I$  ions:  $\text{Ag}1$  is located in a distorted trigonal bipyramid and  $\text{Ag}2$  in a irregular tetragonal pyramid of oxygen atoms (Fig. 1). Calculated values of bond valence sums (BVS; Brown & Altermatt, 1985) were found to be quite different: 0.96 valence units (v.u.) for  $\text{Ag}2$  and 0.87 v.u. for  $\text{Ag}1$ . The observed deviation of the BVS of the latter atom from its chemical valence (expected 1) is due to a high polyhedral distortion caused by the presence of rigid  $(\text{PO}_3)_n$  chains. In this case the BVS values may be seen as a degree of silver "underbonding" and have a concomitant effect on physical properties of the title compound or glassy materials containing silver polyphosphate. The next-nearest coordination spheres of  $\text{Ag}1$  include six adjacent silver atoms, resulting in edge-sharing  $\text{Ag}1$  and  $\text{Ag}2$  polyhedra and other four polyhedra connected through corners. As a result of this linkage, two polyhedral ribbons appear. One spreads parallel to the  $a$ -axis through interconnected  $[\text{Ag}1\text{O}_5]$  polyhedra by sharing a common edge and vertex alternatively, and another spreads parallel to the  $b$ -axis and consist of corner-sharing  $[\text{Ag}1\text{O}_5]$  polyhedra.  $\text{Ag}2$  is remotely surrounded by one  $\text{Ag}1$  and two  $\text{Ag}2$ , resulting in a ribbon of edge-sharing  $[\text{Ag}2\text{O}_5]$  polyhedra that run parallel to the  $c$ -axis. Intersecting these ribbons leads to a three-dimensional network penetrated with tunnels having eight-sided windows. Helical chains  $(\text{PO}_3)_n$  with a repeating unit of four phosphate tetrahedra are located within the tunnels and spiral along the  $2_1$  axes parallel to the  $b$ -axis. Due to the centrosymmetric nature of the structure, adjacent chains are left- and right-helices. As is characteristic for *catena*-polyphosphates (Averbuch-Pouchot, 1993), each of the two  $\text{PO}_4$  tetrahedra displays two types of P—O bond lengths: P—O terminal ranging from 1.479 (2) to 1.4952 (19) Å and P—O bridging from 1.5889 (17) to 1.6074 (18) Å. The corresponding BVS are 4.92 v.u. and 4.95 v.u. for P1 and P2, respectively. The BVS per doubled formula (corresponds to the crystallographically independent atoms in a cell) of positively charged atoms equals to 11.72 v.u., while the chemical charge of the remaining O atoms is equal to -12 valences. This difference is an additional indication of the strain in the structure caused by the presence of rigid phosphate chains.

## S2. Experimental

AgPO<sub>3</sub> was prepared by crystallizing a solution of Ag<sub>3</sub>PO<sub>4</sub> in H<sub>3</sub>PO<sub>4</sub> (84 %<sub>wt</sub>) at a molar ratio Ag/P = 0.01. The thermal treatment included heating the mixture in a graphite crucible at 473 K for 6 h and then cooling to room temperature. After leaching with water, the product consisted of colorless prismatic crystals.

## S3. Refinement

The highest peak and the deepest hole in the final difference map are located at 0.56 Å from Ag1 (1.432 e/Å<sup>3</sup>) and 0.56 Å from Ag1 (-1.858 e/Å<sup>3</sup>), respectively

**Figure 1**

2008)  
Extinction coefficient: 0.0034 (3)

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
