Received 28 March 2011; accepted 13 April 2011

Key indicators: single-crystal X-ray study;  $T = 123\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.015\text{ \AA}$ ; H-atom completeness 97%; disorder in solvent or counterion;  $R$  factor = 0.043;  $wR$  factor = 0.112; data-to-parameter ratio = 18.8.

The crystal structure of the title compound, poly[[((4,7,13,16,21,24-hexaoxa-1,10-diazabicyclo[8.8.8]hexacosane)ruthidium][[(1,4,7,10,13,16-hexaoxacyclooctadecane)ruthidium]di- $\mu$ -ruthidium- $\mu$ -nonastannide] pentaammonia],  $[(\text{Rb}(\text{C}_{18}\text{H}_{36}\text{N}_2\text{O}_6))[\text{Rb}_3\text{Sn}_9(\text{C}_{12}\text{H}_{24}\text{O}_6)\text{C}_{12}\text{H}_{24}\text{O}_6]]\cdot 5\text{NH}_3$ , represents the first ammoniate of a Zintl anion together with two different chelating substances, namely 18-crown-6 and [2.2.2]-cryptand. The involvement of these large molecules in the crystal structure of [Rb(18-crown-6)][Rb([2.2.2]-cryptand)]Rb<sub>2</sub>Sn<sub>9</sub>·5NH<sub>3</sub> leads to the formation of a new structural motif, namely one-dimensionally extended double strands running parallel to [100] and built by Sn<sub>9</sub><sup>4-</sup> cages and Rb<sup>+</sup> cations. The double strands are shielded by 18-crown-6 and [2.2.2]-cryptand. The cations are additionally coordinated by ammonia molecules. One of the four independent Rb<sup>+</sup> cations is disordered over two sets of sites in a 0.74 (2):0.26 (2) ratio.

## Related literature

For a recent review on nine-atom group 14 clusters in solution, see: Scharfe & Fässler (2010). For Zintl clusters in the solid state see: Fässler (2001); Hoch *et al.* (2003). The coordination of two cations by 18-crown-6 usually results in two-dimensional layers (Hauptmann & Fässler, 2002, 2003a,b), when three cations are coordinated by the latter, one-dimensional single strands are observed (Fässler & Hoffmann, 1999). The use of less [2.2.2]-cryptand gives two-dimensional double layers (Hauptmann *et al.*, 2001), whereas larger amounts result in one-dimensional single strands (Burns & Corbett, 1985) or isolated nonastannide clusters without direct cation contacts (Corbett & Edwards, 1977).

## [Rb(18-crown-6)][Rb([2.2.2]-cryptand)]Rb<sub>2</sub>Sn<sub>9</sub>·5NH<sub>3</sub>

**Stefanie Gaertner and Nikolaus Korber**

### S1. Comment

Compounds which contain elements of group 14 elements in negative oxidation states can be obtained by reacting an electropositive metal with the favoured element in solid state reactions at high temperatures. Some of these Zintl phases contain molecular homoatomic clusters preformed in solid state (Hoch *et al.*, 2003, Fassler, 2001). The dissolution of these cluster containing Zintl compounds in an appropriate solvent is a common route to obtain homoatomic building blocks in solution (Scharfe & Fassler, 2010). Dissolving the binary material Rb<sub>12</sub>Sn<sub>17</sub>, which contains four and nine atom clusters of tin, in liquid ammonia in presence of 18-crown-6 and [2.2.2]-cryptand yields a dark red solution, the colour of which is characteristic for polystannides in solution. After storage at 236 K for five months dark red, rod shaped crystals could be isolated, which only include the nine atom clusters Sn<sub>9</sub><sup>+</sup> and four Rb<sup>+</sup>, of which one Rb cation is coordinated by 18-crown-6 and one Rb<sup>+</sup> is situated in the cavity of a [2.2.2]-cryptand molecule. The coordination of two cations by 18-crown-6 usually results in two-dimensional layers (Hauptmann & Fassler, 2003*a,b*; Hauptmann & Fassler, 2002), when three cations are coordinated by the latter, one-dimensional single strands are observed (Fassler & Hoffmann, 1999). The use of less [2.2.2]-cryptand gives two-dimensional double layers (Hauptmann *et al.*, 2001), whereas larger amounts result in one-dimensional single strands (Burns & Corbett, 1985) or isolated nonastannide clusters without direct cation contacts (Corbett & Edwards, 1977). The presence of the two different chelating compounds offers the possibility of a new structural motif in nonastannide compounds. Here, one-dimensional double strands of nonastannide cages linked by Rb<sup>+</sup> (Rb10, Rb12, Rb13) along the crystallographic *a* axis are observed. These double strands are shielded by 18-crown-6 molecules, which surround Rb10 (Fig. 1). [2.2.2]-cryptand molecules around Rb11 isolate the double strands from each other. The coordination spheres of the Rb cations are saturated by ammonia molecules, additionally one ammonia molecule of crystallization is found (Fig. 2).

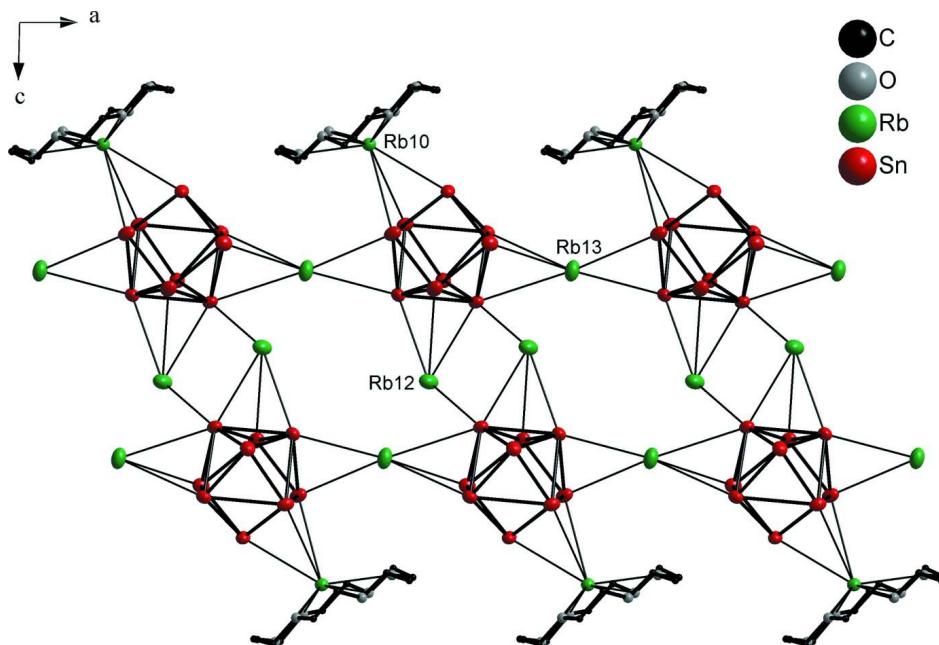

### S2. Experimental

0.36 g Rb<sub>12</sub>Sn<sub>17</sub> (0.115 mmol), 0.06 g 18-crown-6 (0.25 mmol) and 0.09 g [2.2.2]-cryptand (0.25 mmol) were placed under Argon atmosphere in a baked out reaction vessel. Afterwards, 15 ml of dry liquid ammonia were condensed onto the reaction mixture, which yielded a dark red solution. After storage for five months at 236 K, dark red crystals could be obtained.

### S3. Refinement

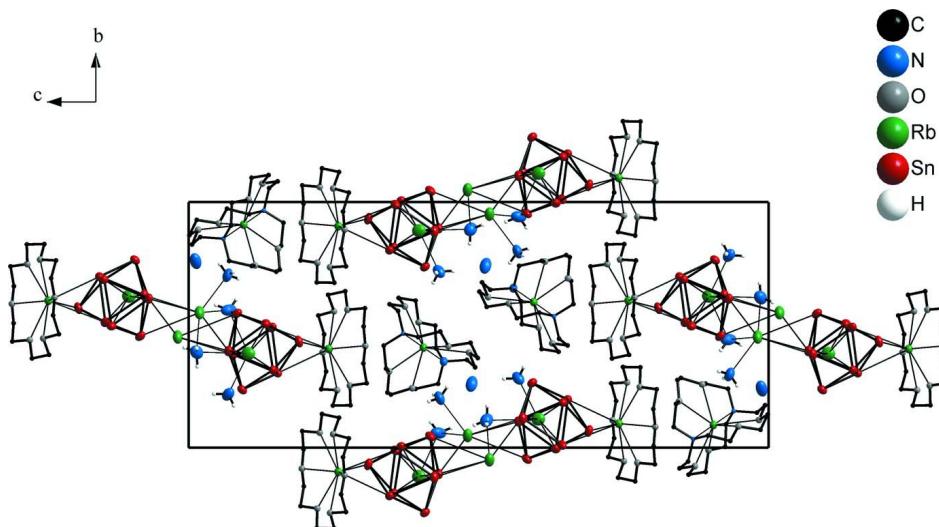

For one Rubidium atom a split model was applied due to large anisotropic displacement, yielding refined soft values of 0.874 (Rb13) respectively 0.126 (Rb14). The H atoms of four ammonia molecules were constructed at geometrically reasonable positions using a riding model (HFIX). For one ammonia molecule, which does not show contacts to cations, it did not seem reasonable to construct H atoms. Due to the extreme sensitivity towards moisture the implacement of a water molecule can be excluded. The H atoms of 18-crown-6 and [2.2.2]-cryptand were also located by using the HFIX

instructions.

**Figure 1**

One-dimensionally extended double strands along the crystallographic *a* axis built by Rb12 and Rb13 (split position is not shown), 18-crown-6 molecules around Rb10 shield the strands. H atoms of 18-crown-6 are omitted; ellipsoids of all non-hydrogen atoms are given with a probability factor of 50%.

**Figure 2**

The unit-cell content of  $[Rb(18\text{-crown}\text{-}6)][Rb([2.2.2]\text{-cryptand})]Rb_2Sn_9 \times 5NH_3$  shows the separation of the strands by [2.2.2]-cryptand molecules around Rb11; the coordination spheres of the Rb cations are saturated by ammonia molecules. H atoms of 18-crown-6 and [2.2.2]-cryptand are omitted; ellipsoids of all non-hydrogen atoms are given with a probability factor of 50%.

*Special details*

**Experimental.** crystal mounting in perfluorether (T. Kottke, D. Stalke, J. Appl. Crystallogr. 26, 1993, p. 615)

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
