Received 4 April 2011; accepted 11 April 2011

Key indicators: single-crystal X-ray study; $T = 150$ K; mean $\sigma(C-C) = 0.006$ Å;
 R factor = 0.026; wR factor = 0.049; data-to-parameter ratio = 24.3.

The title complex, $[Pt(CH_3)_2(SCH_2CH_2CO_2)(C_{10}H_8N_2)]$, is formed by the unusual oxidative addition of the disulfide, R_2S_2 ($R = CH_2CH_2CO_2H$), to (2,2'-bipyridine)dimethylplatinum(II) with elimination of RSH . The product contains an unusual six-membered thiolate–carboxylate chelate ring. This slightly distorted octahedral complex exhibits *cis* angles ranging from 77.55 (11) to 97.30 (8)° due to the presence of the thiolate–carboxylate chelate ring and the constrained bipyridine group. The crystal packing appears to be controlled by a combination of π -stacking [centroid–centroid distance = 3.611 (2) Å] and C–H···O interactions.

(OC-6-35)-(2,2'-Bipyridine- κ^2N,N')dimethyl(3-sulfidopropionato- κ^2S,O)platinum(IV)

Matthew S. McCready and Richard J. Puddephatt

S1. Comment

Activation of the S—S bond of a disulfide, R_2S_2 , has shown significant promise in the areas of medicinal chemistry and catalysis when cleaved by a transition metal complex (Wei *et al.*, 2005). One route of interest for the activation of an S—S bond is the oxidative addition to a transition metal complex, of which there have been many studies involving platinum(II) complexes (Aye *et al.*, 1993; Bonnington *et al.*, 2008). Unexpectedly, the oxidative addition of 3,3'-dithiobipropionic acid led to the formation of a thiolate-carboxylate chelate ring. This type of chelate ring is not without precedent (Henderson *et al.*, 2000; Phillips & Burford, 2008) but the title complex, (I), is the first example of a thiolate-carboxylate chelate with platinum(IV) (McCready & Puddephatt, 2011). In this context, the crystal structure of (I) is presented.

The stereochemistry at the platinum(IV) center is octahedral with two mutually *cis* methyl groups and chelating 2,2'-bipyridine and 3-thiolatopropionato groups (Fig. 1 and Table 1). The distance Pt—N2 = 2.149 (3) Å is significantly longer than Pt—N1 = 2.107 (3) Å, because the methyl group has a higher *trans* influence than the thiolato group. The angles at platinum(IV) between *cis* ligands range from 77.55 (11) to 97.30 (8) °, Table 1, as a result of constraints of the chelate ligands and lie in the expected ranges (Aye *et al.*, 1988; Achar *et al.*, 1993).

The chief intermolecular interactions arise through π -stacking between the bipyridine rings of centrosymmetrically related molecules of (I) (Fig. 2). The mean interplanar spacing between the bipyridine rings comprising the dimer unit is 3.36 Å, which is consistent with observed values of about 3.3 Å for platinum(IV) complexes of 2,2'-bipyridine (Au *et al.*, 2009). The ring centroid(N3-pyridyl)···ring centroid(N4-pyridyl)^A distance = 3.611 (2) Å for A = -x, -y, 1-z. The dimer formation through π -stacking is further stabilized by the presence of a weak C10—H···O2 interaction (Table 2).

S2. Experimental

Dimethyl(2,2'-bipyridine)platinum(II) was prepared according to a previously published procedure by Monaghan and Puddephatt (1984). Spectroscopic Analysis, IR (ν , cm⁻¹, KBr disk): ν (Aromatic CH) = 3107, ν (aliphatic CH) = 2847 and 2781; ν (CC) = 1601, 1465 and 1443. ¹H NMR in acetone-d⁶: δ = 0.97 [s, 6H, ²J(PtH) = 86 Hz, MePt]; 7.70 [dd, 2H, ³J(H₅H₆) = 6 Hz, ³J(H₅H₄) = 7 Hz, H₅]; 8.33 [dd, 2H, ³J(H₄H₅) = 7 Hz, ³J(H₄H₃) = 8 Hz, H₄]; 8.43 [d, 2H, ³J(H₃H₄) = 8 Hz, H₃]; 9.23 [d, 2H, ³J(H₆H₅) = 6 Hz, H₅]. A solution of PtMe₂(bipy) (0.010 g, 0.026 mmol) in minimum acetone was added to a solution of dithiopropionic acid (0.0056 g, 0.026 mmol) in minimum acetone. Mixing of the two solutions led to the formation of a red-brown colour which persists while precipitation of the product is observed. After 30 h the red-orange precipitate can be isolated by decantation of the solvent and was washed with diethyl ether. PtMe₂(bipy) (0.0010 g) was then dissolved in minimal chlorobenzene and added to an NMR analysis tube. To this solution, a buffer layer of chlorobenzene followed by acetone was added in order to slow the rate of diffusion of the subsequently added acetone solution of (0.0006 g) of dithiopropionic acid. The sample was placed in a cool dark place and allowed to crystallize over the

course of two weeks producing crystals of (I). Yields of 68–73% were achieved. Spectroscopic Analysis, IR (ν , cm⁻¹, Bruker Tenser 27 FTIR spectrophotometer as KBr disk): ν (Aromatic CH) = 3107; ν (aliphatic CH) = 2847 and 2781; ν (CC) = 1601, 1465 and 1443; ν (CO) = 1710. ¹H NMR (acetone-d⁶, p.p.m., Mercury 400 MHz NMR spectrometer): δ = 0.50 [s, 3H, ²J(PtH)=74 Hz, MePt *trans* to O]; 1.63 [s, 3H, ²J(PtH) = 69 Hz, MePt *trans* to N]; 2.73 [t, 2H, ³J(HH) = 7 Hz, CH₂]; 2.96 [t, 2H, ³J(HH)=7 Hz, CH₂]; 7.42 – 9.78 [8H, aromatic protons (bipy)]. MALDI-MS (CHCA): m/z = 499 (PtMe₃(NN)(S(CH₂)₂COO)]⁺, m/z = 486 (Complex 1 + H⁺); m/z = 381([PtMe₂(bipy)]⁺). The

S3. Refinement

The C-bound H atoms were placed in calculated positions (C—H 0.95–0.99 Å) and were included in the refinement in the riding model approximation with $U_{\text{iso}}(\text{H})$ values equal to 1.2 $U_{\text{eq}}(\text{C})$. The maximum and minimum residual electron density peaks of 0.92 and -1.42 e Å⁻³, respectively, were located 0.64 Å and 0.74 Å from the Pt1 atom respectively.

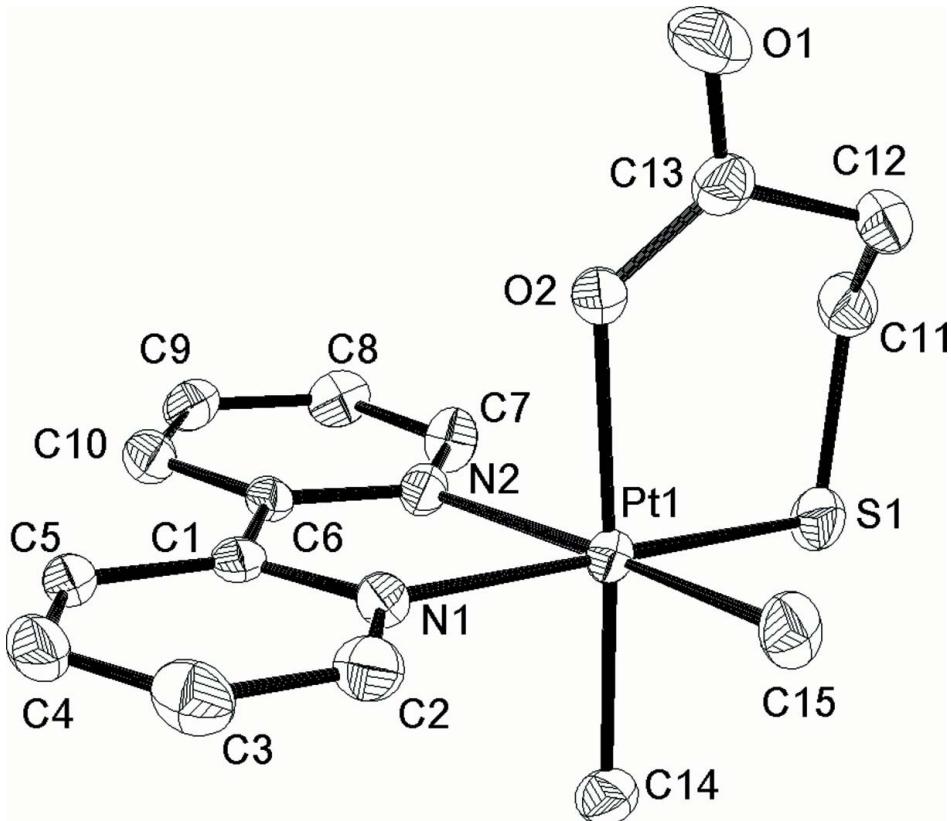

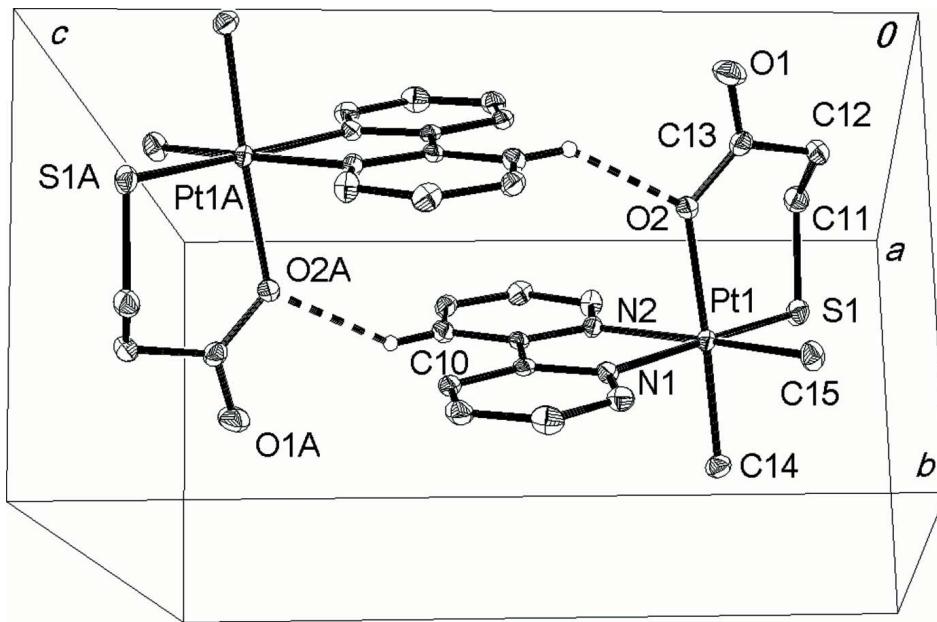

Figure 1

A view of the molecular structure of (I), showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level and hydrogen atoms have been omitted.

**Figure 2**

A dimeric unit in (I) showing its orientation within the unit cell. The molecules are related by a centre of inversion and A = -x, 1 - y, -z+1.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
