Received 17 May 2011; accepted 23 May 2011
Key indicators: single-crystal X-ray study; $T=296 \mathrm{~K}$; mean $\sigma(\mathrm{O}-\mathrm{B})=0.004 \AA$; $R$ factor $=0.037 ; w R$ factor $=0.101$; data-to-parameter ratio $=20.4$.

The title compound contains infinite one-dimensional $\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right]^{3-}$ borophosphate helical ribbons, built up from alternate $\mathrm{BO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra arranged around the $6_{5}$ screw axes. The vertex-sharing $\mathrm{BO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra form a spiral ribbon of four-membered rings in which $\mathrm{BO}_{4}$ and $\mathrm{PO}_{4}$ groups alternate. The ribbons are connected through slightly distorted $\mathrm{MgO}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ octahedra, in which the four O atoms belong to the phosphate groups. The free threads of the helices are occupied by silver ions, which are in an irregular environment surrounded by six O atoms. The central channels of the helices, running along the $c$ axis, are filled with the water molecules. The structure is stabilized by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds between the water molecules and O atoms that are part of the helices. The crystal structure of the title compound is isotopic with other analogous borophosphates such as $A^{\mathrm{I}} M^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right] \cdot \mathrm{H}_{2} \mathrm{O}$, where $A^{\mathrm{I}}=\mathrm{Li}, \mathrm{Na}, \mathrm{K}$ or $\mathrm{NH}_{4}^{+}$ and $M^{\mathrm{II}}=\mathrm{Mg}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$ or Cd .

## S1. Comment

The rich structural chemistry of the borophosphates system has generated considerable contemporary interest as a consequence of the interesting physical and chemical properties of the porous or tunnel structures generally adopted by the inorganic solids which are formed (Kniep et al., 1998, Ewald et al., 2007). Most of these compounds were synthesized with alkali $\left(\mathrm{A}^{\mathrm{I}}\right)$ and transition metal cations ( $M^{\mathrm{II}}$ ), with the general formula $\mathrm{A}^{\mathrm{I}} M^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right] \cdot \mathrm{H}_{2} \mathrm{O}$, under hydrothermal conditions at 443-463 K (Kniep et al. (1997) and Lin et al. (2008)).
The crystal structure of the new synthesized helical borophosphate-hydrate $\mathrm{AgMg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right]$. $\mathrm{H}_{2} \mathrm{O}$ is isotopic with other analogues borophosphates like $\mathrm{A}^{\mathrm{I}} M^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right] . \mathrm{H}_{2} \mathrm{O}\left(\mathrm{A}^{\mathrm{I}}=\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{NH}_{4}^{+}\right.$and $M^{\mathrm{II}}=\mathrm{Mg}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}$, $\mathrm{Zn}, \mathrm{Cd})$ (Menezes et al., (2008)). Fig. 1 represents the plot of the asymmetric unit showing the cationic environment and the connection between different polyhedra. The $\mathrm{BO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra are relatively regular with $\mathrm{B}-\mathrm{O}$ and $\mathrm{P}-\mathrm{O}$ bond lengths ranging from 1.455 (3) $\AA$ to 1.480 (3) $\AA$ and from 1.503 (2) $\AA$ to to 1.569 (2) $\AA$, respectively. Whereas, in the distorted $\mathrm{MgO}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ octahedron, the distances $\mathrm{Mg}-\mathrm{O}$ vary between 2.053 (2) $\AA$ and 2.169 (3) $\AA$. Moreover, the $\mathrm{AgO}_{6}$ polyhedron is more irregular with $\mathrm{Ag}-\mathrm{O}$ distances in the range of 2.462-2.725 (3) $\AA$.
The structure consists of infinite one dimensional helical anionic ribbons $\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right]^{3-}$ constructed by corner-sharing $\mathrm{BO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra, arranged around the $6_{5}$ screw axes. The ribbons borders are connected with $\mathrm{Mg}^{2+}$ cations via the terminal oxygen atoms of the phosphate groups. A three dimensional network is formed by interconnection between the $\left(\mathrm{AgO}_{6}\right)_{\mathrm{n}}$ helices running along [001] and the tetrahedral ribbons via the slightly distorted $\mathrm{MgO}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ octahedra. The central channels of the helices, running along $c$ axis, are filled up with the water molecule as shown in Fig 2. The structure is stabilized by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds between water molecules and O atoms that are part of the helices (Table 1).

## S2. Experimental

The compound was hydrothermally synthesized at $453^{\circ} \mathrm{K}$ for 7 days in a 25 ml Teflon-lined steel autoclave from the mixture of $\mathrm{MgO}, \mathrm{H}_{3} \mathrm{BO}_{3}, \mathrm{H}_{3} \mathrm{PO}_{4}(85 \%), \mathrm{AgNO}_{3}$ and 5 ml of distilled water in the molar ratio of 1:4:6:1:165. The brilliant colourless octahedral crystals were recovered and washed with hot water, then dried in air. Except for boron and hydrogen the presence of the elements were additionally confirmed by EDAX measurements.

## S3. Refinement

The highest peak in the difference map is at $0.76 \AA$ from Ag 1 atom, and the minimum peak is at $0.52 \AA$ from Ag 1 atom.

Figure 1
Partial plot of $\mathrm{AgMg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left[\mathrm{BP}_{2} \mathrm{O}_{8}\right] \mathrm{H}_{2} \mathrm{O}$ crystal structure showing plyhedra linkage. Displacement ellipsoids are drawn at the $50 \%$ probability level. Symmetry codes: (i) $-y+1,-x+1,-z+13 / 6$; (ii) $y-1,-x+y, z+1 / 6$; (iii) $y-1, x,-z+5 / 3$; (iv) $x, x-y+1,-z+11 / 6$; (v) $-x+y-1, y,-z+3 / 2$; (vi) $-x,-x+y,-z+4 / 3$; (vii) $y, x+1,-z+5 / 3$; (viii) $x-y+1,-y+2,-z+2$.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \sigma\left(F^{2}\right)$ is used only for calculating $R$-factors (gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
