(Isopropylamino)(methyl)diphenylphosphonium iodide

Normen Peulecke,* Stephan Peitz, Bernd H. Müller, Anke Spannenberg and Uwe Rosenthal

Leibniz-Institut für Katalyse e. V. an der Universität Rostock, Albert-Einstein-Strasse 29A, 18059 Rostock, Germany

Correspondence e-mail: normen.peulecke@catalysis.de

Received 4 May 2011; accepted 27 May 2011

 Key indicators: single-crystal X-ray study; $T = 150$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å; R factor = 0.019; wR factor = 0.048; data-to-parameter ratio = 22.5.

The title compound, $\text{C}_{16}\text{H}_{21}\text{NP}^+\cdot\text{I}^-$, was obtained by the reaction of $\text{Ph}_2\text{PN}(\text{iPr})\text{P}(\text{Ph})\text{N}(\text{iPr})\text{H}$ with MeI involving cleavage of one of the P–N bonds in diethyl ether. The two phenyl rings form a dihedral angle of $82.98(5)^\circ$. A weak donor–acceptor $\text{N}-\text{H}\cdots\text{I}$ interaction is observed.

(Isopropylamino)(methyl)diphenylphosphonium iodide**Normen Peulecke, Stephan Peitz, Bernd H. Müller, Anke Spannenberg and Uwe Rosenthal****S1. Comment**

Amidophosphonium salts are useful precursors for phosphazenes, which are necessary for the aza-Wittig reaction. They can be synthesized by different methods: addition of alkylhalides or methyltriflate to a phosphorus-nitrogen-single bond (Payne *et al.*, 1965; Mizuta *et al.*, 2007), addition of alkylhalides to a phosphorus-nitrogen double bond (Imrie *et al.*, 1995), *via* intramolecular addition of alkylhalides (Aladzheva *et al.*, 2003) or *via* other routes (Demange *et al.*, 2006). We became interested in this class of compounds, because the starting compound $\text{Ph}_2\text{PN}(\text{iPr})\text{P}(\text{Ph})\text{N}(\text{iPr})\text{H}$ acts as a superb ligand in the chromium catalyzed trimerization of ethene (Peitz *et al.*, 2010). Here we describe the reaction of this ligand with iodomethane. Surprisingly, it is not the expected phosphonium salt with an intact PNPn-framework, but rather the title compound which is formed in this reaction, due to a cleavage of one of the PN-bonds. The reason for this unusual reaction course is unclear.

Two phenyl rings in the molecule of the title compound form a dihedral angle of $82.98(5)^\circ$ (Fig. 1). All angles around the quarternized phosphorus atom are nearly tetrahedral, with the exception of N1—P1—C4 which is significantly widened [$115.25(7)^\circ$]. A weak donor-acceptor interaction $\text{N1—H1A}\cdots\text{I1}$ [N1—H1A 0.80 (2), $\text{H1A}\cdots\text{I1}$ 2.88 (2), $\text{N1}\cdots\text{I1}$ 3.6641 (14) Å, $\text{N1—H1A}\cdots\text{I1}$ $165.1(17)^\circ$] is observed in the structure.

S2. Experimental

0.062 ml (1.0 mmol) of MeI was added to a stirred solution of 286 mg (0.7 mmol) of $\text{Ph}_2\text{PN}(\text{iPr})\text{P}(\text{Ph})\text{N}(\text{iPr})\text{H}$ in 25 ml of diethylether and the resulting solution was stored at room temperature for 48 h. Subsequently, the white precipitate was filtered off, washed with n-hexane and recrystallized in a dichloromethane/n-hexane mixture to yield 154 mg (0.4 mmol) of colourless crystals of the title compound, which were suitable for X-ray crystal structure analysis and fully characterized by standard analytical methods *e.g.* ^{31}P NMR: (CD_2Cl_2): 38,1 p.p.m.

S3. Refinement

H1A which is attached to N1 was found from difference Fourier map and refined isotropically [N1—H1A 0.81 (2) Å]. All other H atoms were placed in idealized positions with $d(\text{C—H}) = 0.98$ (CH_3) and $0.95\text{--}1.00$ Å (CH) and refined using a riding model with $U_{\text{iso}}(\text{H})$ fixed at $1.5 U_{\text{eq}}(\text{C})$ for CH_3 and $1.2 U_{\text{eq}}(\text{C})$ for CH.

 $\Delta\rho_{\min} = -0.43 \text{ e } \text{Å}^{-3}$

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
