## Diisopropylammonium methanesulfonate

Guido J. Reiss* and Michaela K. Meyer

Institut für Anorganische Chemie und Strukturchemie, Lehrstuhl II: Material- und Strukturforschung, Heinrich-Heine-Universität Düsseldorf, Universitätsstrasse 1, D40225 Düsseldorf, Germany
Correspondence e-mail: reissg@uni-duesseldorf.de

Received 15 July 2011; accepted 20 July 2011

Key indicators: single-crystal X-ray study; $T=150 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.027 ; w R$ factor $=0.060 ;$ data-to-parameter ratio $=21.6$.

The title molecular salt, $\mathrm{C}_{6} \mathrm{H}_{16} \mathrm{~N}^{+} \cdot \mathrm{CH}_{3} \mathrm{SO}_{3}{ }^{-}$, has been determined at 150 K . Two diisopropylammonium cations (dipH) and two anions form $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bonded cyclic dimers lying around centers of symmetry. Only two of the three O atoms of the methanesulfonate anion are involved in hydrogen bonding, resulting in slightly longer $\mathrm{S}-\mathrm{O}$ bond lengths. The title structure represents an example of a sulfonate anion that is part of a hydrogen-bonding $R_{4}^{4}(12)$ graph-set motif, which is well known for related dipH acetates. Additionally, the Raman and the IR spectroscopic data for the title compound are presented.

## Diisopropylammonium methanesulfonate

Guido J. Reiss and Michaela K. Meyer

## S1. Comment

More than one hundred structures are listed to date in the Cambridge Crystallographic Database, which include a diisopropylammonium cation ( dipH ). In most cases the dipH cation is the counter cation of bigger anionic species e.g. anionic complexes and clusters. A limited number of structures are reported that are solely constructed by small classical anions and the dipH cation. In these cases the structure type is strongly dependent on the geometry and the ability of these anions to form hydrogen bonds. The structures reported so far range from a quasi-molecular (dipH $)_{2}\left[\mathrm{SiF}_{6}\right]$ (Reiss, 1998), over cyclic dimers for some acetates (e.g.: Sada et al., 2004) and e.g. a substituted phosphate (Summers et al., 1998), to one-dimensional polymers for the halogenides and some pseudo-halogenides (literature cited in Reiss \& Meyer, 2010). Even a two-dimensional hydrogen bonded network for the $(\operatorname{dipH})_{2} \mathrm{SO}_{4}$ (Reiss \& Engel, 2004) and three-dimensional networks for $\operatorname{dipH}\left[\mathrm{IrCl}_{6}\right]$ (Reiss, 2002) and $(\mathrm{dipH})_{2}\left[\mathrm{CdCl}_{4}\right]$ (Reiss, 2010a) have been reported. The asymmetric unit of the title compound, which crystallizes in the centrosymmetric space group $P 2_{1} / n$, consists of one formular unit. The structure is composed of centrosymmetric, hydrogen bonded, cyclic dimers which are composed of two dipH cations and two methanesulfonate anions arranged as rings (Fig. 1). The graph set (Etter et al., 1990) for these hydrogen bonded dimers is $R_{4}{ }^{4}(12)$. All $\mathrm{N}-\mathrm{C}, \mathrm{C}-\mathrm{C}, \mathrm{S}-\mathrm{O}$, and $\mathrm{S}-\mathrm{C}$ bond lengths are generally within the expected range. The two $\mathrm{S}-\mathrm{O}$ bond lengths of the oxygen atoms involved in hydrogen bonding ( O 1 and O 3 ) are longer than the third one which is in accord to our anticipation (Table 1). The $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds with donor-acceptor distances close to $2.79-2.82 \AA$ (Table 2) are in the range of medium strong hydrogen bonds. The $R_{4}{ }^{4}(12)$ hydrogen bonding motif is well known for dipH acetates (Reiss \& Meyer, 2010, Sada et al. 2004). Combinations of the dipH cation with structurally similar anions like $\left[\mathrm{NO}_{3}\right]^{-}$(Reiss, $2010 b$ ), $\left[\mathrm{ClO}_{4}\right]^{-}$(Bajorat \& Reiss, 2007) and various substituted carboxylate anions can be described as the generalized synthon: $\{\mathrm{dipH}\}^{+}\left\{\mathrm{O}_{2} X R_{y}\right\}^{-}(X=\mathrm{C}, \mathrm{Cl}, \mathrm{N} ; y=1,2, R=\mathrm{O}, \mathrm{C})$. The title structure is a further example with this supramolecular synthon and the typical cyclic dimer.

## S2. Experimental

Diisopropylammonium methanesulfonate, $\left(\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}\right)_{2} \mathrm{NH}_{2}\left[\mathrm{CH}_{3} \mathrm{SO}_{3}\right]$ was prepared by the reaction of $0.72 \mathrm{~g}(7.12 \mathrm{mmol})$ diisopropylamine and $1.48 \mathrm{~g}(15.40 \mathrm{mmol})$ methanesulfonic acid at room temperature. From colourless solution small block-shaped crystals were obtained within a few days. A Raman spectrum was measured using a Bruker MULTIRAM spectrometer; Nd:YAG-Laser at 1064 nm ; RT-InGaAS-detector; 4000-70 $\mathrm{cm}^{-1}: 3022(\mathrm{sh}), 2986(v(\mathrm{C}-\mathrm{H})$, s), 2944( $v(\mathrm{C}-\mathrm{H})$, $v s), 2784(v(\mathrm{~N}-\mathrm{H}), \mathrm{w}), 1462(\delta(\mathrm{C}-\mathrm{H}, \mathrm{m}), 1429(\delta(\mathrm{C}-\mathrm{H}, \mathrm{m}), 1350(\mathrm{w}), 1315(\mathrm{w}), 1227(\mathrm{w}), 1183(\mathrm{w}), 1158(\mathrm{w}), 1099(\mathrm{w})$, $1044(v(\mathrm{~S}-\mathrm{O}), v s), 958(\mathrm{w}), 914(\mathrm{w}), 808(\mathrm{~s}), 778(v(\mathrm{C}-\mathrm{S}), \mathrm{s}), 558(\delta(\mathrm{~S}-\mathrm{O}), \mathrm{s}), 528(\mathrm{~m}), 470(\mathrm{~m}), 392(\mathrm{w}), 348(\rho(\mathrm{~S}-\mathrm{O}), \mathrm{br})$, 83( $m$ ). IR data collected on a Digilab FT3400 spectrometer using a MIRacle ATR unit (Pike Technologies); 4000-560 $\mathrm{cm}^{-1}: 3019(v(\mathrm{C}-\mathrm{H}), \mathrm{s}), 2988(\mathrm{sh}), 2941(m), 2870(v(\mathrm{C}-\mathrm{H}), \mathrm{s}), 2781(v(\mathrm{~N}-\mathrm{H}), \mathrm{m}), 2514(\mathrm{~m}), 1625(\mathrm{w}), 1601(\mathrm{w}), 1483(\delta(\mathrm{C}-$ H, m) , 1416(w), 1397 (m), 1331 (w), 1314(w), 1206(vs), 1177(sh), 1153(vs(S-O), vs), 1100(m), 1040(va(S-O), vs), 977(w), 954(w), 837(w), 805(w), 776(v(C-S), s), 551( $\delta(\mathrm{S}-\mathrm{O}) \mathrm{s})$. Band assignments for Raman and IR spectroscopic data were
made by comparing results of earlier work done on sodium- and caesium methanesulfonate (Thomson, 1972), magnesium sulfonate (Genceli Guner et al., 2010) and dipHCl (Reiss \& Meyer 2010).

## S3. Refinement

A single-crystal suitable for structure determination was harvested from the mother liquor and directly transferred into the cooling stream of an Oxford-Xcalibur diffractometer equipped with an EOS-CCD detector. Data collection was performed at 150 K . All hydrogen atoms were located via difference Fourier synthesis. Positional parameters of hydrogen atoms of the $\mathrm{NH}_{2}$ and the CH group were refined freely. All hydrogen atoms belonging to methyl groups were refined using a riding model with restrained angles and $\mathrm{C}-\mathrm{H}$ distances but allowed to rotate about the $\mathrm{C}-\mathrm{C}$ bond. Anisotrope displacement parameters of all non hydrogen atoms and individual isotropic displacement parameters for all hydrogen atoms were refined freely.

## Figure 1

Hydrogen atoms are drawn with an arbitrary radius and the displacement ellipsoids are shown at the $50 \%$ probability level; ' = $1-x,-y,-z$.

## Special details

Experimental. CrysAlisPro, Oxford Diffraction Ltd., Version 1.171.33.52, Empirical absorption correction using spherical harmonics, implemented in SCALE3 ABSPACK.
Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
