Key indicators: single-crystal X-ray study; $T = 298\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; R factor = 0.032; wR factor = 0.075; data-to-parameter ratio = 16.2.

The title coordination polymer, $[\text{Cu}(\text{C}_2\text{H}_4\text{NO}_2)_2]_n$, is two-dimensional and consists of a distorted octahedral copper coordination polyhedron with two bidentate glycine ligands chelating the metal through the O and N atoms in a *trans*-square-planar configuration. The two axial coordination sites are occupied by carbonyl O atoms of neighbouring glycine molecules. The Cu–O distances for the axial O atoms [2.648 (2) and 2.837 (2) \AA] are considerably longer than both the Cu–O [1.9475 (17) and 1.9483 (18) \AA] and Cu–N [1.988 (2) and 1.948 (2) \AA] distances in the equatorial plane, which indicates a strong Jahn–Teller effect. In the crystal, the two-dimensional networks are arranged parallel to (001) and are linked via N–H \cdots O hydrogen bonds, forming a three-dimensional arrangement.

Poly[di- μ -glycinato-copper(II)]: a two-dimensional coordination polymer

Fabienne Gschwind and Martin Jansen

S1. Comment

Different metal glycine complexes and polymeric structures have been known since the 1960's. The first work on a cadmium glycinato complex was done by (Low *et al.*, 1959), and further studies were reported by (Barrie *et al.*, 1993). Mixed metal glycinato complexes with copper(II) were investigated by (Papavinasam, 1991; Davies *et al.*, 2003; Low *et al.*, 1959).

The complexation of simple copper salts to amino acids is a well investigated reaction and various complexes and clusters have been reported (Low *et al.*, 1959; Davies *et al.*, 2003; Aromi *et al.*, 2008; Bi *et al.*, 2006; Zhang *et al.*, 2005). A three-dimensional copper-glycinate coordination polymer has been reported on by (Chen *et al.*, 2009).

While redissolving the copper cluster $[\text{NaCu}_6(\text{gly})_3(\text{ClO}_4)_3(\text{H}_2\text{O})]_n$ (ClO_4)_{2n} (Aromi *et al.*, 2008) in DMSO, blue crystals of the title compound were obtained and were characterized by X-ray diffraction.

The title compound is a two-dimensional coordination polymer (Fig. 1). It consists of a distorted octahedral copper coordination polyhedron with two bidentate glycine ligands chelating the metal through the oxygen and nitrogen atoms (O1, O3, N1, N2) in a *trans* square planar configuration. The two axial coordination sites are occupied by carbonyl oxygen atoms of the neighbouring glycine molecules (O2 and O4). The Cu—O distances are 2.648 (2) Å (Cu1—O2ⁱ) and 2.837 (2) Å (Cu1—O4ⁱⁱ) for the axial oxygen atoms [symmetry codes: (i) -x-1/2, y+1/2, -z+1/2; (ii) -x+1/2, y-1/2, -z+1/2]. In the equatorial plane the Cu—O distances are 1.9474 (15) and 1.9483 (16) Å for Cu1—O1 and Cu1—O3, respectively, while the Cu—N distances are 1.9883 (19) and 1.948 (2) Å for Cu1—N1 and Cu1—N2, respectively. These bond length differences indicate a strong Jahn-Teller effect.

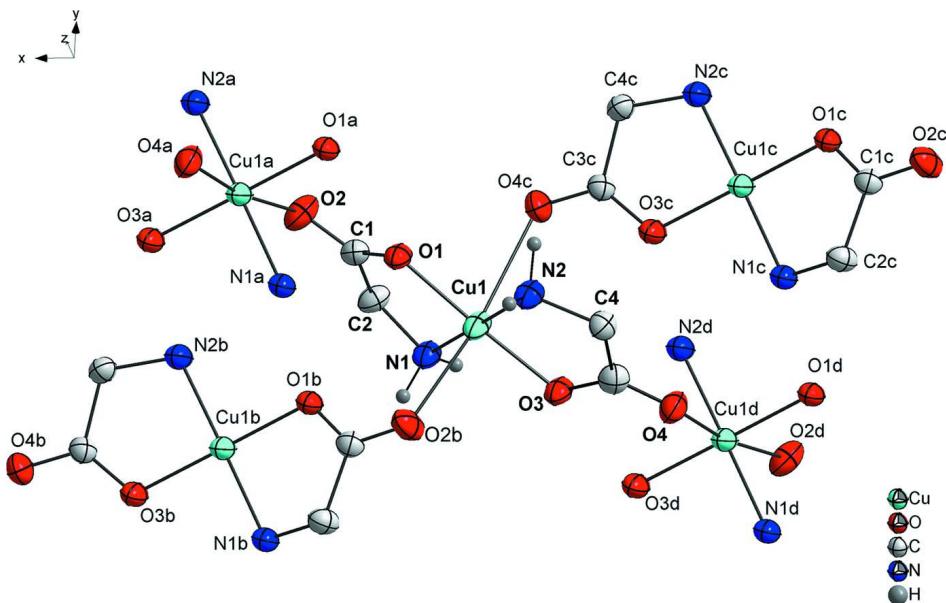

In the crystal the two dimensional networks are linked via N-H···O hydrogen bonds to form a three-dimensional arrangement (Table 1 and Fig. 2).

S2. Experimental

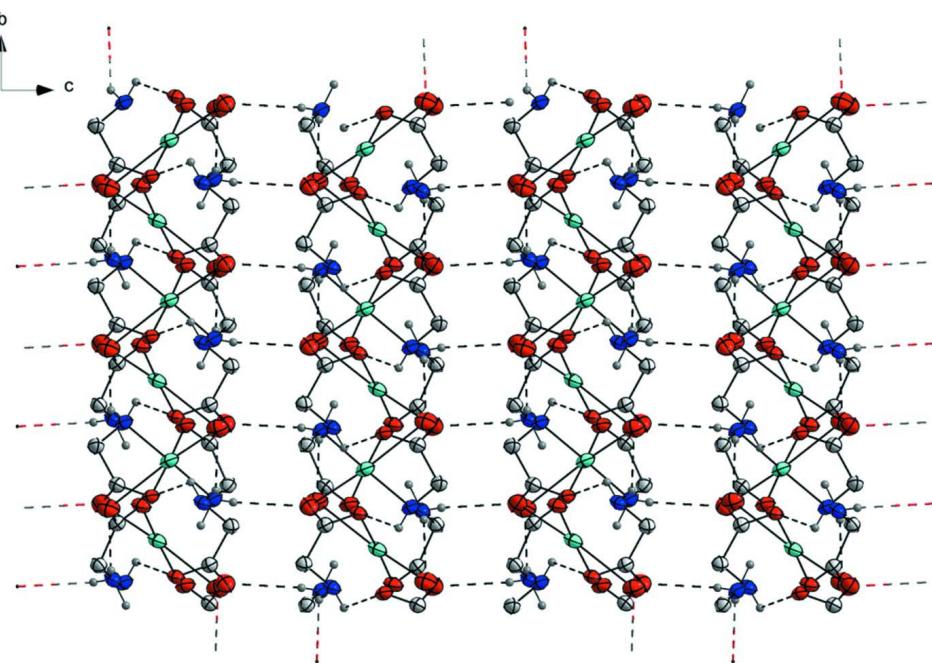

The title compound was prepared by dissolving 20 mg of $[\text{NaCu}_6(\text{gly})_3(\text{ClO}_4)_3(\text{H}_2\text{O})]_n$ (ClO_4)_{2n} (Aromi *et al.*, 2008) in 5 ml DMSO. Crystals could be grown out of the blue solution by slow diffusion of THF.

S3. Refinement

The NH-atoms were located in difference electron-density maps and were freely refined. The C-bound H-atoms were included in calculated positions and treated as riding atoms: C—H = 0.97 Å, with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$.

**Figure 1**

Part of the polymeric structure of the title compound, showing the numbering scheme and the displacement ellipsoids drawn at the 50% probability level [H atoms have been omitted for clarity; symmetry codes: (i) $-x-1/2, y+1/2, -z+1/2$; (ii) $-x+1/2, y-1/2, -z+1/2$].

**Figure 2**

A view along the x-axis of the three-dimensional hydrogen bonded network of the title compound built up from the two-dimensional nets. The N-H...O hydrogen bonds are shown as dashed lines (see Table 1 for details; H-atoms not involved in these reactions have been omitted for clarity).

 $\Delta\rho_{\min} = -0.58 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. Bond distances, angles etc. have been calculated using the rounded fractional coordinates. All su's are estimated from the variances of the (full) variance-covariance matrix. The cell esds are taken into account in the estimation of distances, angles and torsion angles

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
