Hydrogen 4-ammonio-phenylphosphonate

Kerstin Thiele, Christoph Wagner and Kurt Merzweiler*

 Institut für Chemie, Naturwissenschaftliche Fakultät II, Martin-Luther-Universität Halle-Wittenberg, Kurt-Mothes-Strasse 2, 06120 Halle, Germany
 Correspondence e-mail: kurt.merzweiler@chemie.uni-halle.de

Received 8 December 2011; accepted 22 December 2011

 Key indicators: single-crystal X-ray study; $T = 200$ K; mean $\sigma(C-C) = 0.002$ Å; R factor = 0.029; wR factor = 0.063; data-to-parameter ratio = 16.7.

The title compound, $C_6H_8NO_3P$, is isostructural with *p*-arsanilic acid. It exists as the zwitterion $H_3N^+C_6H_4PO_3H^-$. In the crystal, molecules are linked by $O-H\cdots O$ and $N-H\cdots O$ hydrogen-bond bridges, giving a three-dimensional network structure. The strongest hydrogen bonds are formed between adjacent PO_3H groups with $O\cdots O$ distances of 2.577 (2) Å.

Hydrogen 4-ammoniophenylphosphonate

Kerstin Thiele, Christoph Wagner and Kurt Merzweiler

S1. Comment

Compound (I) is isostructural to the corresponding arsenic derivative *p*-arsanilic acid (Nuttall & Hunter, 1996). Like in the case of the arsenic derivative, compound (I) exists in the form of zwitter ions $\text{H}_3\text{N}^+\text{C}_6\text{H}_4\text{PO}_3\text{H}^-$, *i.e.* *p*-ammoniophenylphosphonate. Phosphorus is coordinated nearly tetrahedrally by three O atoms and the carbon atom of the aryl group. The bond lengths between phosphorus and the terminal oxygen atoms O1 and O2 are found to be shorter (1.517 (1) and 1.511 (1) Å) than the P—OH bond (1.569 (1) Å). This is in agreement with the observation in *p*-arsanilic acid with As—O bonds of 1.656 (6), 1.669 (6) and 1.737 (8) Å. The C—N bond length of 1.465 (2) Å is essentially the same as in *p*-arsanilic acid (1.479 (10) Å). This is a typical value for $\text{C}_{\text{aryl}}\text{NH}_3^+$ distances (Allen *et al.*, 1987).

The zwitterions are linked by two different types of hydrogen bonds (Table 1). The strongest hydrogen bonds are observed in the case of O—H...O bridges that are formed between adjacent PO_3H units. Consequently chains with C1,1(4) motifs are formed. Additionally there are N—H...O hydrogen bridges, that are formed between ammonium nitrogen atoms as donors and phosphonate oxygen atoms as acceptors. In this case C1,1(8) structural motifs are found (Bernstein *et al.*, 1995).

As a result of the linkage of NH_3^+ and PO_3H^- groups by hydrogen bonds puckered 6^3 nets are formed. A further (covalent) linkage of the NH_3^+ and PO_3H^- groups by C_6H_4 units, which act as a kind of pillars between the NH_3^+ - PO_3H^- layers, leads to a three-dimensional network. This network contains O atoms as 3- c nodes and P and N atoms as 4- c nodes. According to a topological analysis using TOPOS the three-dimensional net can be described by the Schläfli symbol $\{6^3.8^2.10\}\{6^3.8^3\}\{6^3\}^2$ (Blatov & Proserpio, 2009).

S2. Experimental

4-aminophenylphosphonic acid was synthesized according to a published procedure by Cooper *et al.* (2006). Single crystals were obtained by recrystallization from hot water.

S3. Refinement

H atoms bonded to C were placed in calculated positions with a C—H distance of 0.95 Å, $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. H atoms bonded to N were located from difference fourier maps and refined with N—H distances fixed in the range of 0.91–0.93 Å, $U_{\text{iso}}(\text{H})$ were refined freely. The H atom attached to the phosphonate O atom was located from the difference fourier map and refined freely.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
