Received 24 May 2012; accepted 11 June 2012

Key indicators: single-crystal X-ray study; $T = 173\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; R factor = 0.033; wR factor = 0.094; data-to-parameter ratio = 17.5.

In the title compound, $[\text{Fe}(\text{C}_{10}\text{H}_{15})(\text{C}_6\text{H}_{12}\text{N}_4)(\text{CO})_2]\text{BF}_4^-$, the arrangement around the Fe^{II} atom corresponds to a three-legged piano stool. The pentamethylcyclopentadienyl (Cp^*) ligand occupies three coordination sites, while two CO ligands and one N atom of the hexamethylenetetramine ligand occupy the remaining coordination sites, completing a pseudo-octahedral geometry. Both the complex cation and the BF_4^- anion reside on crystallographic mirror planes. The $\text{Fe}-\text{N}$ bond length is 2.069 (2) and the $\text{Fe}-\text{Cp}^*$ (centroid) distance is 1.7452 (3) \AA .

Dicarbonyl(hexamethylene-1,3,5,7-tetramine- κN^1)(η^5 -pentamethylcyclopentadienyl)iron(II) tetrafluoridoborate

Cyprian M. M'thiruaine, Holger B. Friedrich, Evans O. Changamu and Manuel A. Fernandes

S1. Comment

Hexamethylenetetramine has been used as an antibacterial agent in the treatment of urinary tract infections for several years (Greenwood, 1981; Strom and Jun, 1986) and recently it has found application as a base catalyst to control the porosity and pores size of resorcinol furaldehyde cryogels synthesized in *t*-butanol (Garcia *et al.*, 2010). A number of structures of metal-coordinated hexamethylenetetramine have been reported (Lu *et al.*, 2004; Zheng *et al.*, 2008; Xue *et al.*, 2009) but very few in which hexamethylenetetramine is directly coordinated to iron are known (Allan *et al.*, 1970).

The title compound was obtained as part of our ongoing investigation of the reactions of substitutionally unsaturated metal complexes with nitrogen donor ligands (M'thiruaine *et al.*, 2012a; M'thiruaine *et al.*, 2012b). The synthesis and characterization data was previously reported by us, but its crystal structure is not known. To the best of our knowledge the structure of the title compound is the first of the hexamethylenetetramine complex containing the $Cp^*(CO)_2Fe$ moiety to be reported. It exhibits a typical three legged piano stool structure with Fe^{II} coordinated by hexamethylenetetramine through the nitrogen atom, in which the coordination geometry around Fe can be described as distorted octahedral with three sites occupied by the η^5 -pentamethylcyclopentadienyl ligand, while the two CO ligands and hexamethylenetetramine occupy the remaining three sites to complete the octahedron (Fig 1). Its structure is similar to those of the anionic 1,3,5-triaza-7-phosphadamantane (PTA) complexes $[CpFe(CN)_2(PTA)]^-$, $[CpFe(CN)_2(PTAH)]^-$ (Darensbourg *et al.*, 2003) and that of neutral $[CpW(CO)_2(PTA)H]$ (Shafiq *et al.*, 2000).

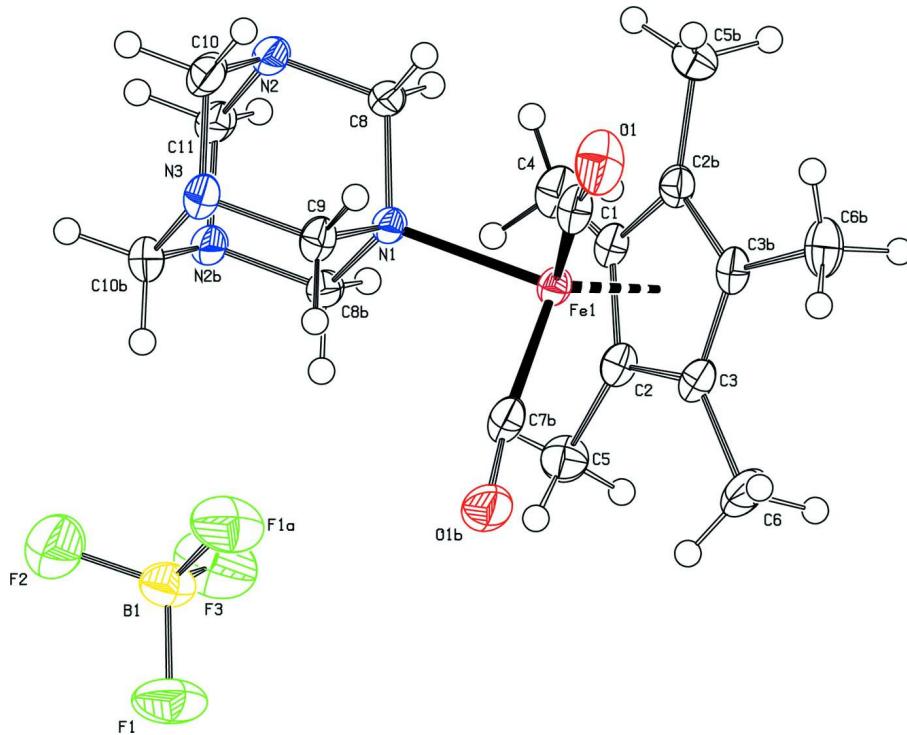

Both the iron complex and the BF_4^- anion crystallize on mirror planes at $b=0.25$ and $b=0.75$ in the crystal structure of the title compound. In the case of the iron complex, the mirror plane goes through the iron atom and bisects the pentadienyl ligand and tertraamine equally, with the carbonyl atoms being located on either side of the mirror plane. In the case of the BF_4^- anion, the boron atom and two of the fluorine atoms (F2 and F3) are located on the mirror plane, while the remaining fluorine atoms are located at either side of the mirror. Consequently, the asymmetric unit of the title compound contains half a monocationic molecule and half a counter-anion. From a molecular structure point of view, the Fe—N bond was found to have a length of 2.069 (2) Å, which is slightly shorter than the 2.0817 (17) and 2.0858 (18) Å distances reported for the dinuclear complex $[\{Cp(CO)_2Fe\}_2\{N_4(CH_2)_6\}]^{2+}$ (M'thiruaine *et al.*, 2012a) and 2.092 (4) Å reported for $[(CO)_4Fe\{N_2(CH_2)_6\}]$ (Matos and Verkade, 2003).

S2. Experimental

The title compound was prepared according to a reported procedure (M'thiruaine *et al.* 2012a) and crystals were grown by layering a concentrated solution of the compound in acetone with Et_2O and the mixture kept undisturbed in the dark for four weeks.

S3. Refinement

Non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full matrix least-square calculations on F^2 using *SHEXTL*. Hydrogen atoms were first located in the difference map then positioned geometrically and allowed to ride on their respective parent atoms.

Special details

Experimental. face indexed absorption corrections carried out with XPREP; Bruker, 2005)

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
