Received 12 July 2012; accepted 24 October 2012

Key indicators: single-crystal X-ray study;  $T = 296$  K; mean  $\sigma(\text{C}-\text{C}) = 0.004$  Å;  $R$  factor = 0.045;  $wR$  factor = 0.095; data-to-parameter ratio = 15.8.

The title compound,  $\{[\text{Cu}(\text{C}_{17}\text{H}_{11}\text{N}_2\text{O}_3)_2(\text{H}_2\text{O})]\cdot 2\text{H}_2\text{O}\}_n$ , is a two-dimensional polymer. The  $\text{Cu}^{2+}$  ion lies on the crystallographic twofold axis. The coordination sphere of the  $\text{Cu}^{2+}$  ion can be described as a distorted square pyramid. All of the H atoms in the amide group and lattice water molecules participate in O—H···O or N—H···O hydrogen bonding to strengthen the two-dimensional framework of the polymer.

## Poly[[aquabis[ $\mu_2$ -6-(pyridine-3-carboxamido)naphthalene-2-carboxylato]copper(II)] dihydrate]

Yun-Sung Song and Soon W. Lee

### S1. Comment

Coordination polymers are prepared by employing a wide variety of linking ligands possessing pyridyl–pyridyl, pyridyl–amine, furan–furan, thiophene–thiophene, or pyridyl–carboxylate terminals. For instance, bis(pyridyl)- and dicarboxylate-type linking ligands have long been utilized in preparing such polymers (Robin & Fromm, 2006). In particular, those containing the pyridyl–carboxylate terminals are intriguing due to the presence of both a harder carboxylate oxygen donor and a softer pyridyl nitrogen donor in them. The ligands of this type were employed to prepare unique polymers containing both *d*- and *f*-block metals within their frameworks (Hu *et al.*, 2012; Chen *et al.*, 2010; Tang *et al.*, 2010; Yue *et al.*, 2011; Zhu *et al.*, 2010). 6-(Nicotinamido)-2-naphthoic acid (HL) belongs to the pyridyl–carboxylate-type linking ligands, and we recently reported its preparation and structure (Song & Lee, 2012). Our research group also reported the molecular structures of two other related linking ligands (Han & Lee, 2012; Zheng & Lee, 2012). We report herein the structure of a two-dimensional Cu polymer of the HL ligand, which is the first *d*-block coordination polymer of this ligand.

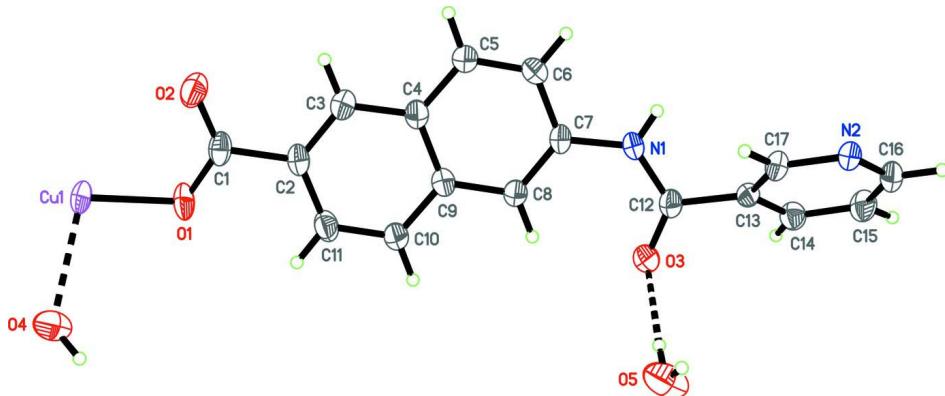

Fig. 1 shows an asymmetric unit of the title polymer, which consists of one half  $\text{Cu}^{2+}$  ion, one 6-(nicotinamido)-2-naphthoato ligand (*L*), one half aqua ligand, and one lattice water molecule. The Cu1 and O4 atoms lie on the crystallographic twofold axis, and the remaining atoms occupy general positions. The  $\text{Cu}^{2+}$  ion is coordinated to two oxygen atoms from two ligands and two nitrogen atoms from another two ligands to form a distorted square plane. The Cu1–O4 length (2.490 (3) Å), which is represented by a dotted line in Fig. 1, is extremely long, considering the covalent radii of Cu (1.28 Å) and O (0.66 Å) atoms. The van der Waals radii of Cu and O atoms are 1.40 and 1.52 Å, respectively, and therefore the Cu1–O4 bond may be best described as a strong van der Waals contact. Consequently, the coordination sphere of the  $\text{Cu}^{2+}$  ion may be thought of as square pyramidal, if the Cu1–O4 van der Waals contact is included. The molecular plane, defined by the two O and two N atoms, is extremely distorted from the planarity with the average atomic displacement of 0.328 (1) Å. Two carboxylate oxygen atoms act differently; one (O1) is coordinated to the  $\text{Cu}^{2+}$  ion and the other (O2) acts as a H-bond acceptor. The terminal carboxylate and pyridyl groups are bonded to the  $\text{Cu}^{2+}$  ions, indicating that this ligand behaves as a linking ligand. The amide group (–CONH–) does not coordinate to the metal ion, and the carbonyl oxygen (O3) acts as a H-bond acceptor and the N–H bond behaves as a H-bond donor. In fact, all of the hydrogen atoms in the amide group and lattice water molecule participate in the hydrogen bonds of the O–H···O or N–H···O types (Table 1). Fig. 2 shows a projection of the title polymer along the *c*-axis. The repeat unit consists of four ligands and four  $\text{Cu}^{2+}$  ions. This unit contains 56 atoms (4  $\text{Cu}^{2+}$  ions and 52 ligand atoms) with the  $\text{Cu}^{2+}\cdots\text{Cu}^{2+}$  separation of 15.2045 (4) Å. The repeat units are connected by the ligands to form a 2-D layer in the [110] direction.

**S2. Experimental**

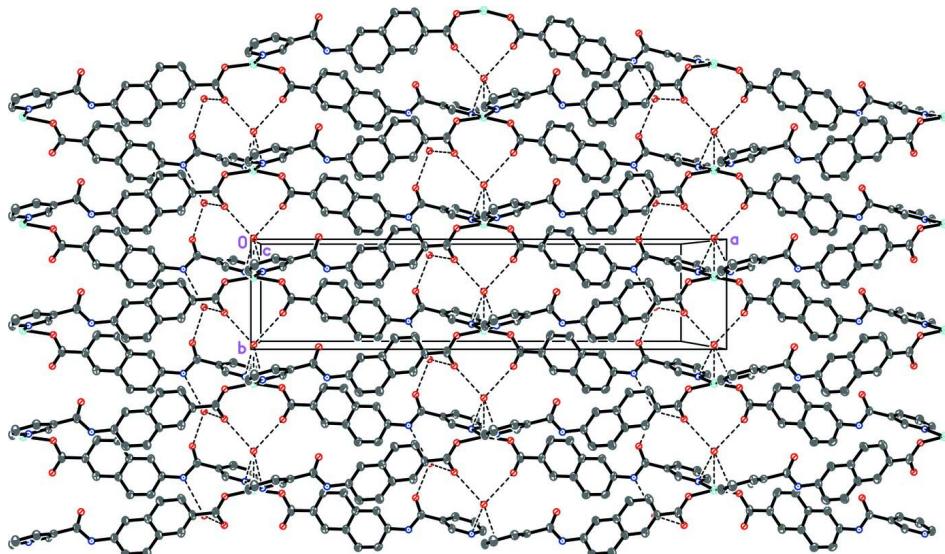

A mixture of Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O (48.3 mg, 0.2 mmol) and 6-(nicotinamido)-2-naphthoic acid (58.4 mg, 0.2 mmol) in H<sub>2</sub>O (20 ml) was sealed in a 24 ml Teflon-lined vessel. The reaction mixture was heated 150 °C for 72 h and then slowly air-cooled to room temperature for 24 h. The resulting green crystals were isolated by filtration, washed by methanol (10 ml × 3), and then air-dried to give the title compound (19 mg, 0.027 mmol, 27% yield). mp: 586–589 K. IR (KBr, cm<sup>-1</sup>): 3474 (w), 2897 (w), 2633 (w), 2383 (w), 2298 (w), 2084 (w), 1805 (w), 1660 (m), 1580 (m), 1483 (m), 1353 (m), 1204 (w), 1108 (w), 1049 (w), 951 (w), 886 (w), 824 (w), 772 (w), 749 (w), 702 (w), 625 (w), 457 (w).

**S3. Refinement**

C-bound H atoms were positioned geometrically [C—H = 0.93 Å] and allowed to ride on their parent atoms, with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ . H-atoms participating in the H-bonds were located in a difference Fourier map and refined freely.

**Figure 1**

An asymmetric unit of the title compound showing the atomic numbering and 50% probability displacement ellipsoids.

**Figure 2**

Packing diagram of the title compound, showing a 2-D layer in the [110] direction. Dotted lines represent hydrogen bonds.

*Special details*

**Geometry.** All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
