Received 24 November 2012; accepted 6 December 2012

Key indicators: single-crystal X-ray study;  $T = 173\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.008\text{ \AA}$ ; disorder in solvent or counterion;  $R$  factor = 0.030;  $wR$  factor = 0.065; data-to-parameter ratio = 17.9.

The asymmetric unit of the title compound,  $[\text{AuCl}(\text{C}_{31}\text{H}_{32}\text{NP})]\cdot0.25\text{CHCl}_3$ , contains two independent complex molecules and half a chloroform solvent molecule, which is disordered across an inversion center. The  $\text{Au}^{\text{I}}$  ions are each coordinated in a slightly distorted linear environment, with  $\text{P}-\text{Au}-\text{Cl}$  angles of  $177.20(4)$  and  $178.54(4)^{\circ}$ .

## **Chlorido{N-[2-(diphenylphosphanyl)benzylidene]-2,6-diisopropylaniline- $\kappa P$ }gold(I) chloroform 0.25-solvate**

**Haleden Chiririwa and Wade L. Davis**

### S1. Comment

Studies of gold(I) complexes have been related to anti-arthritis (Shaw, 1999), anti-tumor (Barnard *et al.*, 2004) and antimicrobial physiological activities (Nomiya *et al.*, 2003). The treatment of diseases with gold complexes (called chrysotherapy) can be traced back to early times (Cowan, 1993). The mechanistic approach regarding the action of gold drugs is still a matter of interest and research, however they remain the most effective second line treatment for rheumatoid arthritis (Parish, 1992; Fricker, 1996). This led to the development of a gold complex called auranofin, which was found to be an experimental chrysotherapeutic agent and was clinically effective in the treatment of rheumatoid arthritis (Finkelstein *et al.*, 1976). Our group has recently been involved in the development of novel Au(I) complexes with iminophosphine ligands and these have shown promising activity when evaluated against two oesophageal cancer cell lines (Chiririwa *et al.*, 2013).

The structure of the title compound (Fig. 1) was determined to establish the coordination properties of the 2-(diphenylphosphanyl)benzylidene)-2,6-diisopropylbenzenamine ligand with gold. The asymmetric unit consists of two crystallographically independent complex molecules. The Au—P bond distances of 2.2354 (10) and 2.2267 (10) Å agree well with reported values (Williams *et al.*, 2007; Chiririwa & Muller, 2012). The chloroform solvent molecule is disordered across an inversion centre.

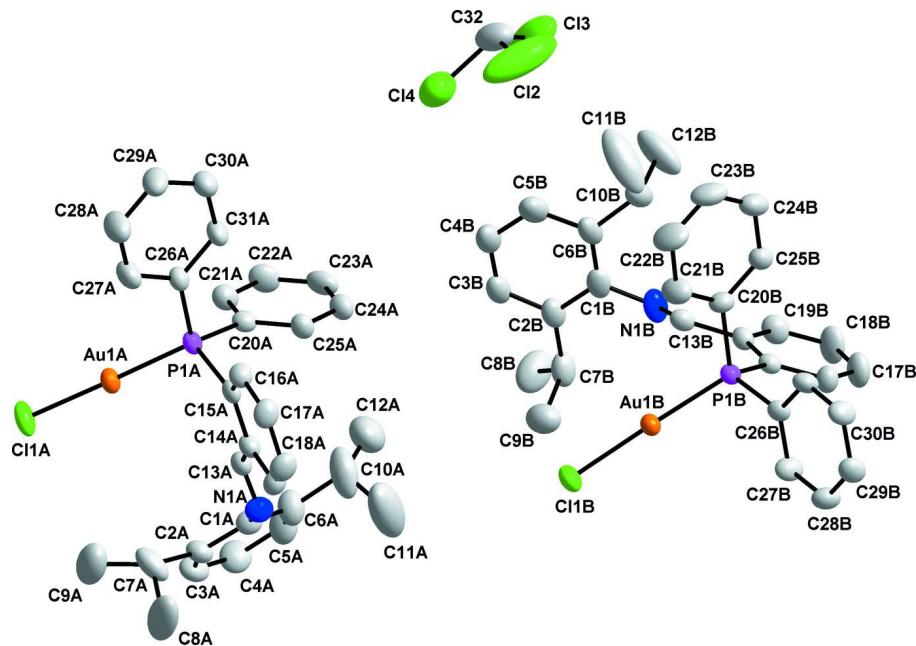

### S2. Experimental

The iminophosphine ligand was synthesized in high yields from the Schiff-base condensation reaction of 2-(diphenylphosphanyl)benzaldehyde with 2,6-diisopropylaniline in CH<sub>2</sub>Cl<sub>2</sub> at room temperature (Mogorosi *et al.*, 2011; Reddy *et al.*, 2002). The Au precursor was synthesized by slow drop wise addition of tetrahydrothiophene (THT) to a solution of HAuCl<sub>4</sub>·4H<sub>2</sub>O in EtOH (Uson & Laguna, 1986). To a dry CH<sub>2</sub>Cl<sub>2</sub> (10 ml) solution of the precursor [Au(tht)Cl] (tht = tetrahydrothiophene) was added an equimolar amount of 2-(diphenylphosphanyl)benzylidene)-2,6 diisopropylbenzenamine in CH<sub>2</sub>Cl<sub>2</sub> (10 ml), and stirred at room temperature for 2 hrs. The solvent was reduced under reduced pressure and on addition of hexane, the product was filtered off and washed with Et<sub>2</sub>O (2 × 5 ml) and dried under vacuum for 4 hrs affording a yellow precipitate. Crystals suitable for X-ray structure determination were obtained by recrystallization from a CHCl<sub>3</sub>/hexane mixture at room temperature. <sup>31</sup>P NMR: 26.64 (*s*). IR (KBr): 1628 cm<sup>-1</sup> (C=N, imine).

### S3. Refinement

All H atoms were included in calculated positions with C—H = 0.95–1.00 Å and included in the refinement with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  or  $1.5U_{\text{eq}}(\text{C}_{\text{methyl}})$ . The chloroform solvate molecule is disordered over an inversion centre, H atom connectivity was correctly assigned by using a PART -1 instruction in SHELXL97 (Sheldrick, 2008). Occupancies of each

disordered component was constrained to 50% conforming to the imposed crystallographic symmetry. No additional geometrical or thermal ellipsoid restraints were employed in the final refinement cycles.

**Figure 1**

Molecular structure of the title complex, showing 50% probability displacement ellipsoids. The chloroform solvent molecule is half occupancy. There are two crystallographic independent molecules labelled as A and B in the asymmetric unit. All hydrogen atoms are omitted for clarity.

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
