Received 25 April 2013; accepted 28 April 2013

Key indicators: single-crystal X-ray study; $T = 120$ K; mean $\sigma(C-C) = 0.004$ Å; disorder in solvent or counterion; R factor = 0.035; wR factor = 0.065; data-to-parameter ratio = 16.9.

In the title compound, $(C_5H_6N)[Fe(NCS)_4(C_5H_5N)_2]$, the Fe^{III} ion is coordinated by four thiocyanate N atoms and two pyridine N atoms in a *trans* arrangement, forming an FeN_6 polyhedron with a slightly distorted octahedral geometry. Charge balance is achieved by one pyridinium cation bound to the complex anion *via* N–H···S hydrogen bonding. The asymmetric unit consists of one Fe^{III} cation, four thiocyanate anions, two coordinated pyridine molecules and one pyridinium cation. The structure exhibits π – π interactions between pyridine rings [centroid–centroid distances = 3.7267 (2), 3.7811 (2) and 3.8924 (2) Å]. The N atom and a neighboring C atom of the pyridinium cation are statistically disordered with an occupancy ratio of 0.58 (2):0.42 (2).

S1. Comment

Molecular assemblies consisting of cationic and anionic modules are of great interest for crystal engineering and molecular magnetism (Strotmeyer *et al.*, 2003; Fritsky *et al.*, 2004). Target properties of such compounds can be tuned by different types of intermolecular interactions, such as coordination and hydrogen bonds, π – π and lone pair – π contacts, *etc.* (Fritsky *et al.*, 1998; Kanderal *et al.*, 2005). In certain cases, even the existence of spin crossover in these complexes can be observed. Therefore, Fe^{II} isothiocyanate complexes with aromatic N-donor ligands attract much attention considering the possible metal ion spin state modulation by variation of a ligand (Gamez *et al.*, 2009). Herein, we attempted to synthesize Fe^{II} thiocyanate complex with 1,5-naphthyridine, however, the reaction of it and [Fe^{II}(NCS)₂(py)₄] (py = pyridine) in CHCl₃ in air led to the oxidation of Fe^{II} and to the formation of the title compound.

The compound consists of complex anion [Fe(NCS)₄(py)₂]⁻ and pyridinium cation the N7 atom of which is disordered over two alternative sites with the occupancy ratio of 0.58 (2): 0.42 (2). The Fe^{III} ion is sixfold coordinated by four N atoms of thiocyanate anions forming the equatorial plane and two N atoms of two pyridine ligands occupying axial positions (Fig. 1). The distances between Fe^{III} ion and N atoms of the thiocyanate anions are shorter than those between Fe^{III} and N atoms of the pyridine ligands (Table 1), hence FeN₆ octahedron is slightly distorted. A similar distortion of the coordination polyhedron was reported for the related compound (Hpy)[Fe(NCS)₄(py)₂]₄(cnpz).(py), where cnpz = pyrazine-2-carbonitrile (Shylin *et al.*, 2013). The thiocyanate ligands are only bound through N atoms and are quasi-linear, while the Fe–NCS linkages are bent [Fe1—N3—C11 = 162.43 (19) $^\circ$, Fe1—N4—C12 = 161.67 (19) $^\circ$, Fe1—N5—C13 = 165.7 (2) $^\circ$, Fe1—N6—C14 = 158.7 (2) $^\circ$]. These structural features are typical for the complexes where the NCS group is N-bound (Petrusenko *et al.*, 1997). The C—N and C—C bond lengths in the coordinated pyridine ligands are normal and close to the values observed in the related structures (Moroz *et al.*, 2010; Penkova *et al.*, 2010).

In the title compound pyridine ligands and pyridinium cations interact with one another *via* π – π stacking, with distances between the centroids of 3.7267 (2), 3.7811 (2) and 3.8924 (2) Å (Fig. 2). Pyridinium cations are also bound to the anionic complex through a number of N—H···S hydrogen bonds (Table 2).

S2. Experimental

Crystals of the title compound were obtained by adding 1,5-naphthyridine (26 mg, 0.2 mmol) to tetrakis(pyridine)bis(isothiocyanato)iron(II) [Fe(NCS)₂(py)₄] (48.8 mg, 0.1 mmol) in CHCl₃ (5 ml). The solution was left to evaporate in air. In one day this yielded red crystals that were collected, washed with water and dried in air. Yield is 16 mg (30% relative to Fe).

S3. Refinement

The N atom of the pyridinium cation was disordered over two alternative sites with the occupancy ratio of 0.58/0.42. Hydrogen atoms were positioned geometrically and constrained to ride on their parent atoms, with C—H = 0.95 and N—

$H = 0.88 \text{ \AA}$, and $U_{\text{iso}} = 1.2 U_{\text{eq}}(\text{C}, \text{N})$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
