Received 5 March 2013; accepted 12 June 2013
Key indicators: single-crystal X-ray study; $T=100 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.035 ; w R$ factor $=0.095$; data-to-parameter ratio $=17.8$.

The title compound, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}$, displays two predominant hydrogen-bonding interactions in the crystal structure. The first is between the unprotonated imidazole N atom of one molecule and the hydroxy H atom of an adjacent molecule. The second is between the hydroxy O atom of one molecule and the imidazole $\mathrm{N}-\mathrm{H}$ group of a corresponding molecule. These interactions lead to the formation of a two-dimnensional network parallel to $(10 \overline{1}) . \mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions also occur.

## S1. Comment

Imidazole ligands have been used in coordination chemistry with great success over the last twenty years (Huff et al., 1993). These successes can be attributed to how the nitrogen in imidazole assists in the formation of metal complexes (Fujita et al., 1994). Imidazole-containing metal complexes have a variety of applications, such as redox mediators in enzyme-based electrochemical sensors (Fan et al., 2000). A few examples of imidazole complex compounds with biological applications have been reported (Bauman and Wang, 1964). Histidine, an essential amino acid, and histamine, a bioorganic compound that acts as neurotransmitter, both involve ( $1 H$-imidazol-5-yl)methanol in their respective synthesizes (Darby et al., 1942). Here we report on a new imidazole compound, the hydroxymethyl-substituted imidazole, the title compound, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}$. The bond lengths and bond angles are within normal ranges in the molecular structure of this compound (Fig. 1). The compound forms hydrogen bonds of 1.985 (8) Å between the nitrogen (N1) on the imidazole ring of one molecule and the hydrogen (H1') of the hydroxyl on an adjacent molecule (Fig. 2). Hydrogen bonding also takes place between the oxygen (O1") on the hydroxyl group of one molecule and the hydrogen (H2) bonded to a nitrogen (N2) on the imidazole ring of a corresponding molecule. This bond measures 1.921 (1) $\AA$ (Fig. 3).

## S2. Experimental

Approximately 100 mg of the target compound was dissolved in 2 ml of a $50 \%$ methanol: $50 \%$ toluene solution. The solution was allowed to evaporate slowly for two weeks until clear, colorless crystals formed. A crystal was isolated and analyzed on a Bruker $A P E X$ II CCD single-crystal X-ray diffractometer.

## S3. Refinement

The structure was solved using direct methods (Bruker, 2011).

Figure 1
Thermal ellipsoid plot at $50 \%$ probability.

Figure 2
The title structure is stabilized by hydrogen bonds between $\mathrm{N1}^{\prime}$ and H 1 , which each measure 1.985 (8) Å. Oxygen atoms are shown in red, carbon atoms in black, hydrogen atoms in pink, and nitrogen atoms in blue.

Figure 3
Hydrogen bonding between the oxygen ( $\mathrm{O} 1{ }^{\prime \prime}$ ) on the hydroxyl group of one molecule and the hydrogen ( H 2 ) bonded to a nitrogen (N2) on the imidazole ring of a corresponding molecule measures 1.921 (1) $\AA$.

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.035$
$w R\left(F^{2}\right)=0.095$
$S=1.07$
1158 reflections
65 parameters
0 restraints
Primary atom site location: structure-invariant direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from neighbouring sites
H -atom parameters constrained
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.0511 P)^{2}+0.6749 P\right]$ where $P=\left(F_{0}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}=0.002$
$\Delta \rho_{\text {max }}=0.35$ e $^{-3} \AA^{-3}$
$\Delta \rho_{\text {min }}=-0.27 \mathrm{e}^{-3}$

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of ( $F^{2}$ ) against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
