Received 5 March 2013; accepted 5 June 2013

Key indicators: single-crystal X-ray study; $T=100 \mathrm{~K}$; mean $\sigma(\mathrm{Te}-\mathrm{O})=0.004 \AA$; disorder in main residue; $R$ factor $=0.034 ; w R$ factor $=0.079$; data-to-parameter ratio $=15.6$.

The title compound, $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{4} \mathrm{Te}$, crystallized from a solution of $\mathrm{Te}^{4+}$ in ethylene glycol. The $\mathrm{Te}^{\mathrm{IV}}$ atom is in a distorted seesaw coordination defined by four O atoms from two different ethyleneglycate ligands. The C atoms of the ethyleneglycate ligands are disorderd over two positions, with population parameters of 50.3 (6) and 49.7 (6)\% indicating a statistical distribution. Due to the possibility to transform the primitive monoclinic unit cell into a metrically orthorhombic $C$ unit cell, the data are twinned and were refined with the twin law $\overline{1} 00$ / $0 \overline{1} 0 / 101$ with the relative scale factor refining to $1.82(4) \%$ for the minor component.

## S1. Comment

Solutions of $\mathrm{Te}^{4+}$ in ethylene glycol are interesting for the purposes of electrodeposition of Te and Te compounds (Nguyen et al., 2012, Wu et al., 2013). During such electrodeposition experiments we have noticed a large number of colourless crystals on the walls of the glass flask. We report here the crystal structure of these crystals.
The title compound, $\mathrm{Te}\left(\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}_{2}\right)_{2}$, crystallized with one molecule in the asymmetric unit. The Te atom is in a distorted seesaw coordination defined by four O atoms from two different ethyleneglycato ligands (Fig. 1, Table 1). The carbon atoms of the ethyleneglycato ligands are disorderd over two positions, with the major component comprising 50.3 (6)\% of the total. The angle between the best planes through atoms $\mathrm{Te} 1-\mathrm{O} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{O} 4$ and $\mathrm{Te} 1-\mathrm{O} 5-\mathrm{C} 6-\mathrm{C} 7-\mathrm{O} 8$ is $85.4(3)^{\circ}$. For the second position the angle between the best planes through $\mathrm{Te} 1-\mathrm{O} 1-\mathrm{C} 7^{\prime}-\mathrm{C}^{\prime}-\mathrm{O} 8$ and $\mathrm{Te} 1-\mathrm{O} 4-$ C2'-C3'—O5 is $85.6(3)^{\circ}$.
Crystal structures of seven similar four coordinate $\mathrm{Te}^{4+}$ complexes with oxo ligands have previously been reported by Day \& Holmes (1981), Yosef et al. (2007), Annan et al. (1992), Fleischer \& Schollmeyer (2001), Betz et al. (2008) and Lindqvist (1967), all of which have a distorted seesaw geometry of the Te centre. The geometries or the Te-O bond lengths in these structures do not differ remarkably from those in the title compound. The most closely related compound is the octamethyl derivative bis(1,1,2,2-tetramethyleneglycolato- $O, O^{\prime}$ )tellurium(IV) (Day \& Holmes, 1981), in which the $\mathrm{Te}-\mathrm{O}$ bond lengths are, within error, the same as in the title compound. The $\mathrm{O}-\mathrm{Te}-\mathrm{O}$ bond angles that define the seesaw are $105.59^{\circ}$ and $153.53^{\circ}$ compared to $94.83(14)^{\circ}$ and $159.65(13)^{\circ}$ in the title compound. In tetrakis(methoxy)tellurium(IV) (Betz et al., 2008), the $\mathrm{O}-\mathrm{Te}-\mathrm{O}$ bond angles are $89.99^{\circ}$ and $171.42^{\circ}$.

## S2. Experimental

Equal volumes of a 1 M solution of $\mathrm{TeCl}_{4}$ in ethylene glycol and a 4 M solution of $\mathrm{AgNO}_{3}$ in ethylene glycol were mixed together, ensuring that $\mathrm{AgNO}_{3}$ was in a slight excess. The resulting precipitate of AgCl was removed by filtration. Excess $\mathrm{Ag}^{+}$ions in the remaining solution were removed by electrodeposition on a Pt working electrode at a constant potential of -0.1 V versus Ag and the solution used in electrodeposition experiments (Wu et al., 2013). When the solution was left to stand for a period of two months, a large number of colourless crystals of the title compound slowly appeared on the walls of the glass flask.

## S3. Refinement

The H atoms were included using a riding model, with $\mathrm{C}-\mathrm{H}$ distances of $0.99 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$. The disorder of the ligands was modelled with two atomic positions for each C atom and the relative occupancy of these two positions refined as a least-squares parameter. The population parameters of 50.3 (6) and 49.7 (6)\% indicate a statistical distribution. Constraints were applied to the displacement parameters of the C atoms to keep the respective atoms from the two disorder components the same. The unit-cell dimensions are such that it is possible to transform the primitive
monoclinic unit cell into a metrically orthorhombic $C$ unit cell, however the high $R_{\text {int }}$ for the higher Laue class shows that the Laue symmetry of the data is unequivocally monoclinic. There is however slight twinning due to these metrics and the data were refined with the twin law $\overline{1} 00 / 0 \overline{1} 0 / 101$ with the relative scale factor refining to 1.82 (4)\% for the minor component.. At the end of the refinement there was a residual difference electron density peak of 3.93 e $\AA^{-3}$, which was located close to the Te atom. Although careful consideration was given to the unit cell determination and the absorption correction, this peak could not be eliminated.

Figure 1
View of the asymmetric unit of $\mathrm{Te}\left(\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right)_{2}$ showing the molecular structure and the disorder of the ligands. Solid bonds belong to one disorder component and open bonds to the other component ( $\mathrm{Te}-\mathrm{O}$ bonds are common to both components). For emphasis and to avoid confusion it should be noted that the $\left(\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right)$ ligands are disordered and the ligand is not macrocyclic.

$\theta_{\text {max }}=28.9^{\circ}, \theta_{\text {min }}=3.1^{\circ}$
$h=-8 \rightarrow 7$
$k=-8 \rightarrow 8$
$l=-20 \rightarrow 18$

Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from neighbouring sites
H -atom parameters constrained
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.034 P)^{2}\right]$
where $P=\left(F_{\mathrm{o}}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}=0.001$
$\Delta \rho_{\text {max }}=3.93$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.97 \mathrm{e}^{-3}$

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors (gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
