Correspondence e-mail: wangzhiguo224865@163.com

Received 20 May 2013; accepted 18 June 2013

Key indicators: single-crystal X-ray study; $T=173 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.004 \mathrm{~A}$; $R$ factor $=0.019 ; w R$ factor $=0.048$; data-to-parameter ratio $=16.4$.

The asymmetric unit of the title coordination complex, $\left[\mathrm{Ag}_{2} \mathrm{Br}_{2}\left(\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{~N}_{2}\right)_{2}\right]_{n}$, comprises a monodentate 1-ethylimidazole ligand, an $\mathrm{Ag}^{+}$cation and a $\mu_{3}$-bridging $\mathrm{Br}^{-}$anion, giving a distorted tetrahedral $\mathrm{AgNBr}_{3}$ stereochemistry about the $\mathrm{Ag}^{+}$ cation $[\mathrm{Ag}-\mathrm{N}=2.247$ (2) $\AA$ and $\mathrm{Ag}-\mathrm{Br}=2.7372$ (4)2.7523 (4) A]. Two bridging bromide anions generate the dimeric $\left[\mathrm{Ag}_{2} \mathrm{Br}_{2}\left(\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{~N}\right)_{2}\right]$ repeat unit $[\mathrm{Ag} \cdots \mathrm{Ag}=$ 3.0028 (5) A], while a third $\mathrm{Br}^{-}$anion links the units through corner sharing in an inversion-related $\mathrm{Ag}_{2} \mathrm{Br}_{2}$ association [Ag..Ag $=3.0407(4) \AA$ ], generating a one-dimensional ribbon step-polymer structure, extending along the $c$ axis.

## S1. Comment

Silver and other transition metal $N$-heterocyclic carbene complexes have played an important role in development of metal-carbene systems for transmetalation reactions. Recent reviews dealing with silver $N$-heterocyclic carbenes were published by Arnold (2002) and Lin \& Vasam (2004). The products differ depending upon reaction conditions and the imidazolium salt used. Deprotonation by use of $\mathrm{Ag}_{2} \mathrm{O}$ has been the most widely used method in the syntheses of N heterocyclic carbene complexes of silver. The procedure can be accomplished using the reaction of $\mathrm{Ag}_{2} \mathrm{O}$ with the imidazolium salt in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution. The 3-diethylbenzole N -heterocyclic carbene complexes of silver have been successfully synthesized by the reaction of the 1,3-diethylbenzolium salt with $\mathrm{Ag}_{2} \mathrm{O}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (Wang \& Lin, 1998). In an attempt to prepare similar $N$-heterocyclic carbene complexes of silver by the reaction of $\mathrm{Ag}_{2} \mathrm{O}$ with 1,2-dibromocyclohexane and 1-ethylimidazole in DMSO solution, we obtained the title compound, $\left[\left(\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{~N}\right)_{2} \mathrm{Ag}_{2} \mathrm{Br}_{2}\right]_{\mathrm{n}}$, instead and the synthesis and crystal structure are reported herein. Although the stair polymers of $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)_{4} \mathrm{Ag}_{4} \mathrm{I}_{4}\right]_{\mathrm{n}}($ Liu et al., 2003) and 1-allyl-3-methylimidazole carbine silver iodide (Chen \& Liu, 2003) have recently been reported, their structural features are different from that of the title complex being formed through triple and quadruple halide bridges with $\mathrm{Ag} \cdots \mathrm{Ag}$ interactions.
In the title complex the asymmetric unit comprises one monodentate 1-ethylimidazole ligand, an $\mathrm{Ag}^{+}$cation and a doubly bridging $\mathrm{Br}^{-}$anion, giving a distorted tetrahedral $\mathrm{AgNBr}_{3}$ stereochemistry about silver $[\mathrm{Ag}-\mathrm{N}, 2.247(2) \AA \AA ; \mathrm{Ag}-$ $\mathrm{Br}, 2.7372$ (4)-2.7752 (3) $\AA$ and bond angle range about Ag of 106.78 (6)-113.55 (5) ${ }^{\circ}$ ] (Fig. 1). These $\mathrm{Ag} — \mathrm{Br}$ bond distances are considerably longer than those found in the $\left[\mathrm{Ag}_{2} \mathrm{Br}_{4}\right]^{2-}$ complex anion [2.518 (2) $\AA$ ] (Helgesson \& Jagner, 1990). The Ag1—N1 bond [2.247 (2) $\AA$ ] is somewhat shorter than $2.335 \AA$ found in the pyridine silver iodide polymer $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)_{4} \mathrm{Ag}_{4} \mathrm{I}_{4}\right]_{\mathrm{n}}$ (Liu et al., 2003). The dimeric $\mathrm{Ag}_{2} \mathrm{Br}_{2}$ repeating core unit in the title complex is generated through a double Br bridge, giving an $\mathrm{Ag} \cdots \mathrm{Ag}^{\mathrm{i}}$ separation of $3.0028(\mathrm{r}) \AA$ [for symmetry code (i): $-x+1, y,-z$ ) $+1 / 2$ ]. The fourmembered core ring so formed is very similar to that in the complex anion $\left[\mathrm{Ag}_{4} \mathrm{Br}_{8}\right]^{4-}$ (Helgesson \& Jagner, 1991).
The basic coomplex is extended into a one-dimensional step-polymer ribbon structure through centrosymmetric $\mathrm{Ag}-\mathrm{Br}$ and $\mathrm{Br}-\mathrm{Ag}$ bonds along the $c$ axial direction (Fig. 2). Within these cyclic $\mathrm{Ag}_{2} \mathrm{Br}_{2}$ linkages, the $\mathrm{Ag} \cdots \mathrm{Ag}^{\text {iii }}$ separation is 3.0407 (4) $\AA$ [for symmetry code (iii): $-x+1,-y+1,-z$ ].

## S2. Experimental

1,2-Dibromocyclohexane ( $2.42 \mathrm{~g}, 10 \mathrm{mmol}$ ) was added to a solution of 1-ethylimidazole ( $1.92 \mathrm{~g}, 20 \mathrm{mmol}$ ) in DMSO $(100 \mathrm{ml})$ at room temperature and stirred for 2 h , after which $\mathrm{Ag}_{2} \mathrm{O}(2.32 \mathrm{~g}, 10 \mathrm{mmol})$ was added and the mixture was refluxed for 3 h with stirring. The volume of the solution was reduced to 50 ml under vacuum, the residue was removed by filtration and the filtrate was kept at room temperature for a few days. Colorless crystals of the title compound were obtained after slow evaporation ( $1.74 \mathrm{~g}, 30 \%$ yield). (mp: 335 K ). ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): 9.42(\mathrm{~m}, 1 \mathrm{H}), 6.88(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}), 6.84$ (s, $1 H, \mathrm{CH}$ ), 4.54(s, $2 H, \mathrm{CH}_{2}$ ), $3.65\left(\mathrm{~s}, 3 H, \mathrm{CH}_{3}\right)$ p.p.m. Anal. calcd.: C, 21.12; H, 2.82; N, 9.86\%; found: C, $21.05 ; \mathrm{H}$,
2.76; N, 9.75\%.

## S3. Refinement

The H atoms attached to C atoms of the imidazole ring were positioned geometrically and allowed to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}=0.95 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$. Methylene and methyl H atoms were likewise positioned geometrically $\left(\mathrm{C}-\mathrm{H}=0.99\right.$ and $0.98 \AA$, respectively) and also refined as riding atoms, and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$

Figure 1
The atom numbering scheme for the contents of the asymmetric unit in the title complex. Displacement ellipsoids are drawn at the $30 \%$ probability level. For symmetry codes: (i) $-x+1, y,-z$ ) $-1 / 2]$; (ii) $x,-y, z)+1 / 2$.

Figure 2
The step-polymeric structure of the title complex, extending along the $c$ axial direction.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
