Received 20 April 2014; accepted 14 May 2014

Key indicators: single-crystal X-ray study; $T = 100\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.008\text{ \AA}$; R factor = 0.043; wR factor = 0.100; data-to-parameter ratio = 18.4.

The title compound, $(\text{C}_6\text{H}_{14}\text{N})_2[\text{Sn}(\text{C}_6\text{H}_5)_2\text{Cl}_4]$, contains cyclohexylammonium cations in general positions and a stannate(IV) anion that is located on a twofold rotation axis. The Sn^{IV} atom in the complex anion is surrounded by four Cl^- ligands and two *trans*-phenyl groups in a distorted octahedral configuration. The anions are connected with the cations through $\text{N}-\text{H}\cdots\text{Cl}$ hydrogen bonds. Every cation is involved in three $\text{N}-\text{H}\cdots\text{Cl}$ bonds to the chloride ligands of three different anions, and each chloride ligand is linked to two cations. This arrangement leads to a layered structure parallel to (010).

Bis(cyclohexylammonium) tetrachloridodiphenylstannate(IV)

Modou Sarr, Carina Merkens, Aminata Diassé-Sarr, Libasse Diop and Ulli Englert

S1. Comment

Our interest for organotin(IV) compounds (Sarr *et al.*, 2013*a,b*) is related to applications found in various fields like in medicine, industry or agriculture (Evans & Karpel, 1985; Kapoor *et al.*, 2005).

The crystal structure of the title compound, $2(\text{C}_6\text{H}_{14}\text{N})^+[\text{Sn}(\text{C}_6\text{H}_5)_2\text{Cl}_4]^{2-}$, consists of cyclohexylammonium cations and a $[\text{SnPh}_2\text{Cl}_4]^{2-}$ anion that is located on a twofold rotation axis. The Sn^{IV} atom is bonded to two *trans*-phenyl groups and four chloride ligands in a distorted octahedral geometry (Fig. 1). For reasons of symmetry, the Sn—C bond lengths are equal and amount to 2.142 (5) Å. The two independent Sn—Cl bond lengths have very similar values [2.5685 (16) and 2.5842 (17) Å] and may be compared to the values of 2.5722 (6) and 2.5796 (6) Å reported for bis(trimethylammonium) tetrachloridodiphenylstannate(IV) (Diop *et al.*, 2011). The C—Sn—C angle (179.6 (4) °) is linear within experimental error. The angles in the equatorial plane of the pseudo-octahedron deviate slightly from 90° [$\text{Cl}1-\text{Sn}1-\text{Cl}1^i = 91.12 (8)$ °; $\text{Cl}1-\text{Sn}1-\text{Cl}2 = 89.41 (5)$ °, $i = -x, -y, z$]. The tetrachloridodiphenylstannate(IV anion, $[\text{SnPh}_2\text{Cl}_4]^{2-}$, in its *cis* or *trans* configurations has been reported previously by several authors with different counter cations (Garcia-Seijo *et al.*, 2001; Fernandez *et al.*, 2002; Venkatraman *et al.*, 2004; Diop *et al.*, 2011).

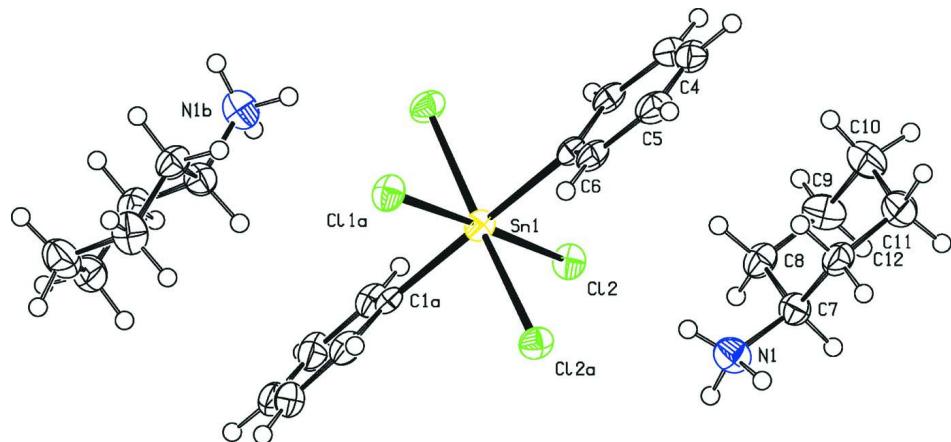

Each cation in the title compound is linked to Cl atoms of three different anions through classical N—H···Cl hydrogen bonds (Fig. 2, Table 1), leading to a layered arrangement parallel to (010).

S2. Experimental

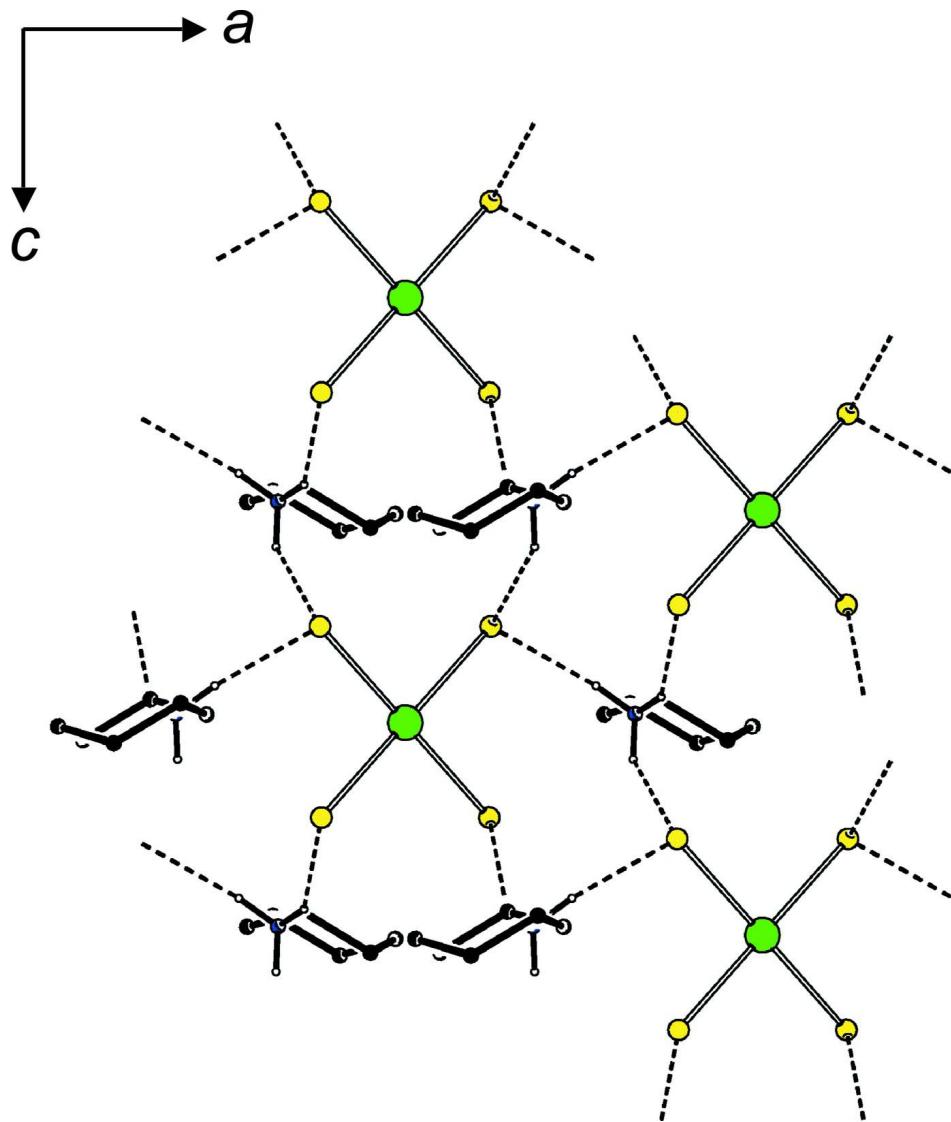

Equimolar amounts of cyclohexylamin and oxalic were dissolved in water; crystals formed by slow evaporation. Their elemental analyses, calculated/ % (found/ %), C: 53.31 (53.05); %H: 9.91(10.28); %N: 8.88(8.40), suggest the composition $(\text{CyNH}_3)_2(\text{C}_2\text{O}_4)_3/2\text{H}_2\text{O}$. Crystals suitable for the X-ray determination of the title compound were obtained by mixing methanolic solutions of $(\text{CyNH}_3)_2(\text{C}_2\text{O}_4)_3/2\text{H}_2\text{O}$ and SnPh_2Cl_2 in a 1:1 ratio and subsequent slow solvent evaporation.

S3. Refinement

Hydrogen atoms bonded to carbon were treated as riding with $\text{C}-\text{H} = 0.95$ Å for aryl-CH and $\text{C}-\text{H} = 0.99$ Å for CH_2 groups. Isotropic displacement parameters for these hydrogen atoms were constrained to $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. Hydrogen atoms bonded to nitrogen were located in a difference Fourier map; N—H distances were restrained to 0.91 (3) Å. Isotropic displacement parameters for these hydrogen atoms were constrained to $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{N})$. Refinement showed that the crystal under investigation was an inversion twin; the major domain is associated with a volume fraction of 0.77 (5).

 $w = 1/[\sigma^2(F_o^2) + (0.020P)^2]$
 where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} = 0.004$
 $\Delta\rho_{\max} = 1.92 \text{ e } \text{\AA}^{-3}$
 $\Delta\rho_{\min} = -0.67 \text{ e } \text{\AA}^{-3}$
 Absolute structure: Flack (1983), 1281 Friedel pairs
 Absolute structure parameter: 0.23 (5)

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
