The title compound $\left[\mathrm{Co}\left(\mathrm{C}_{22} \mathrm{H}_{26} \mathrm{~N}_{4} \mathrm{O}_{4}\right)\right] \mathrm{PF}_{6}$, commonly known as $[\mathrm{Co}(\mathrm{bpcd})] \mathrm{PF}_{6}$, where bpcd ${ }^{2-}$ is derived from the historical ligand name $N, N^{\prime}$-bis(2-pyridyl-methyl)-trans-1,2-diaminocyclohexane- $N, N^{\prime}$-diacetate, crystallized by slow evaporation of a saturated acetonitrile solution in air. The cation of the hexafluoridophosphate salt has the $\mathrm{Co}^{\text {III }}$ atom in a distorted octahedral coordination geometry provided by an $\mathrm{N}_{4} \mathrm{O}_{2}$ donor atom set. The acetate groups, which are oriented trans with respect to each other, exhibit monodentate coordination whereas the pyridyl N atoms are coordinating in a cis configuration. The geometry of the cation is compared to the geometries of other diamino diacetate complexes with $\mathrm{Co}^{\mathrm{III}}$.

## 1. Chemical context

Polyaminocarboxylic acids are of considerable interest as complexation reagents for a variety of metal ions in a wide range of applications (Weaver \& Kappelmann, 1964; Weiner \& Thakur, 1995; Caravan et al., 1997a,b; Geraldes, 1999; Heitzmann et al., 2009). The title compound, [Co(bpcd)]$\mathrm{PF}_{6}$, (I), was prepared from $N, N^{\prime}$-bis(2-pyridylmethyl)-trans-1,2-diaminocyclohexane- $N, N^{\prime}$-diacetic acid ( $\mathrm{H}_{2} \mathrm{bpcd}$ ), a symmetrically disubstituted polyaminocarboxylic acid featuring a chiral trans-diaminocyclohexane backbone.

The ligand precursor, $\mathrm{H}_{2}$ bpcd, belongs to a relatively small group of diamino diacetic acids that contain softer aromatic nitrogen donor groups (Fig. 1) (Caravan et al., 1997a; Heitzmann et al., 2009; Kissel et al., 2014). The preorganized ligand precursor $\mathrm{H}_{2}$ bpcd is of interest as a novel candidate for selective and efficient actinide(III)/lanthanide(III) separations. Preorganization of a ligand can reduce the pre-orientation energy required for metal ion complexation and provide improved metal-ligand complex stability (Rizkalla et al., 1987; Choppin et al., 2006; Ogden et al., 2012). The addition of aromatic functionalities, such as pyridine and pyrazine, may increase ligand selectivity for softer metal ions and provide

B

Figure 1
The diamino diacetic acids, $\mathrm{H}_{2}$ bped (A) and gem- $\mathrm{H}_{2}$ bped (B), where bped stands for bis(2-pyridylmethyl)-1,2-diaminoethane diacetate, $\mathrm{H}_{2}$ bpcd (C), and $\mathrm{H}_{2}$ bppd (D), where bppd stands for bis(2-pyridylmeth-yl)-1,3-diaminopropane diacetate.
greater stability towards radiolysis (Heitzmann et al., 2009). The members of this group of diacetic acids, however, differ in the nature of the diamine backbone.

The ethylenediamine backbone is a classic scaffold that has been used for the construction of many polydentate ligands. The amine N atoms are ideal for functionalization, which allows different donor atom groups to be incorporated into a ligand's design. The close proximity of the diamine nitrogens also maximizes the number of possible five- and six-membered chelate rings capable of forming upon metal ion complexation. $\mathrm{H}_{2}$ bped (A) is a hexadentate 2-pyridylmethyl-substituted diacetic acid based on this classic scaffold (Lacoste et al., 1965; Caravan et al., 1997a). gem- $\mathrm{H}_{2}$ bped (B) is a very closely related 2-pyridylmethyl-substituted diacetic acid that is also based on the ethylenediamine scaffold. In this case, however, both pyridine substituents are bonded to the same amine N atom (Heitzmann et al., 2009). The $\mathrm{C}-\mathrm{C}$ chain length between
the N atoms in the diamine backbone of these ligands allows for the formation of five-membered chelate rings. Hancock has shown the formation of five-membered chelate rings to be more favourable for larger metal ions than for smaller metal ions (Hancock \& Martell, 1989). The ligand precursor, $\mathrm{H}_{2} \mathrm{bpcd}$ (C), for the title compound is similar to A and B , but it incorporates the ethylenediamine backbone into a cyclohexyl group. Restricted rotation about the $\mathrm{C}-\mathrm{C}$ bonds in the cyclohexane ring fixes the positions of the trans diamine nitrogen atoms and favourably preorganizes these donor groups for metal ion complexation. Consequently, the trans amine groups are constrained into a conformation that is preoriented favorably for binding and results in a complex of increased stability (Rizkalla et al., 1987; Choppin et al., 2006; Ogden et al., 2012). In contrast, $\mathrm{H}_{2} \mathrm{bppd}$ (D) features a 1,3diaminopropane backbone that provides greater flexibility compared to A, B, or C with their shorter backbones. Further, the increased chain length of the propylene linker allows a sixmembered chelate ring to form upon metal complexation. Formation of six-membered chelate rings in complexes with smaller metal ions has been shown to increase the stability of the complex relative to five-membered rings (Hancock \& Martell, 1989). Here, we report the structure of a $\mathrm{Co}^{\text {III }}$ complex with bpcd ${ }^{2-}$, C.

## 2. Structural commentary

The structure of the $[\mathrm{Co}(\mathrm{bpcd})]^{+}$cation in the title compound is shown in Fig. 2 and selected geometric parameters are listed in Table 1. The cation is very similar to the structures of the $[\mathrm{Co}(\mathrm{bped})]^{+}$and $[\mathrm{Co}(\mathrm{bppd})]^{+}$complex ions. Nearly all of the $\mathrm{Co}-\mathrm{O}_{\mathrm{ac}}$ bond lengths for the five structures given in Table 1 are within experimental error of each other. One of the $\mathrm{Co}-$ $\mathrm{O}_{\mathrm{ac}}$ bond lengths in the $[\mathrm{Co}(\mathrm{bppd})]^{+}$cation, however, is slightly shorter than the others. The $\mathrm{C}-\mathrm{O}$ and $\mathrm{C}=\mathrm{O}$ bond lengths are also quite similar. There are, however, some variations in the bond lengths and angles as shown in Tables 1 and 2. The $\mathrm{Co}-\mathrm{N}_{\mathrm{am}}$ bond length in the $[\mathrm{Co}(\mathrm{bpcd})]^{+}$cation is slightly shorter than the $\mathrm{Co}-\mathrm{N}_{\mathrm{am}}$ bond lengths reported for the two $[\mathrm{Co}(\mathrm{bppd})]^{+}$cations given in Table 1. They are,

Figure 2
View of the cation of the title structure, $[\mathrm{Co}(\mathrm{bpcd})]^{+}$. Here and in subsequent figures, displacement ellipsoids are shown at the $50 \%$ probability level. H atoms are shown as circles of arbitrary size. [Symmetry code: (i) $-x+1,-y+\frac{1}{2}, z$.]
however, slightly longer than those reported for the $[\mathrm{Co}(\text { bped })]^{+}$structures. Similarly, the $\mathrm{Nam}_{\mathrm{a} 1}-\mathrm{Co}-\mathrm{N}_{\mathrm{am} 2}$ bond angle in $[\mathrm{Co}(\mathrm{bpcd})]^{+}$is close to ideal $\left(90^{\circ}\right)$, whereas the $\mathrm{N}_{\mathrm{am} 1}-$ $\mathrm{Co}-\mathrm{N}_{\mathrm{am} 2}$ angles in the $[\mathrm{Co}(\mathrm{bppd})]^{+}$structures are somewhat larger than ideal and somewhat smaller than ideal in the $[\mathrm{Co} \text { (bped) }]^{+}$structures (Table 2). The $\mathrm{O}_{\mathrm{ac} 1}-\mathrm{Co}-\mathrm{O}_{\mathrm{ac} 2}$ bond angles for the five structures in Table 2 are all close to ideal $\left(180^{\circ}\right)$, with the largest deviation from linearity observed in the $[\mathrm{Co}(\mathrm{bpcd})]^{+}$cation. The $176.1^{\circ} \mathrm{O}_{\mathrm{ac} 1}-\mathrm{Co}-\mathrm{O}_{\mathrm{ac} 2}$ bond angle in $[\mathrm{Co}(\mathrm{bpcd})]^{+}$is $2^{\circ}$ smaller than the average $\left(178.5^{\circ}\right)$ of the bond angles reported for the $[\mathrm{Co}(\text { bped })]^{+}$and $[\mathrm{Co}(\text { bppd })]^{+}$ cations. Finally, the $\mathrm{Co}^{\mathrm{III}}$ in the title compound is situated directly in the $\mathrm{N}_{4}$ plane of the equatorial nitrogen atoms, whereas in three of the other four structures the $\mathrm{Co}^{\mathrm{III}}$ lays slightly out-of the plane (Table 1). The solid-state structural parameters for $[\mathrm{Co}(\mathrm{bpcd})]^{+}$, which are very similar to those for

Figure 3
View of the molecular components of the title structure, $[\mathrm{Co}(\mathrm{bpcd})] \mathrm{PF}_{6}$. [Symmetry code: (i) $-x+1,-y+\frac{1}{2}, z$.]
$\mathrm{Co}(\mathrm{bped})^{+}$, suggest that the ligand precusor $\mathrm{H}_{2}(\mathrm{bpcd})$, with its preorganized arrangement, may provide greater metal ion complex stability as well as be selective for actinides(III) over lanthanides(III) as demonstrated for gem $-\mathrm{H}_{2}$ (bped). (Heitzmann et al., 2009)

## 3. Supramolecular features

The structure of the title compound (Fig. 3) exists in the solid state as an intricate network of anions and cations closely associated through many short interactions. Hydrogenbonding interactions are listed in Table 3. Each $\mathrm{PF}_{6}{ }^{-}$anion is in close contact with six cations: three of the four unique F atoms interact with two neighboring cations while the remaining atom, F 4 , has a long interaction $(2.29 \AA$ ) with only the $\mathrm{C}-\mathrm{H} 9 A$ bond of the cyclohexyl ring of one cation. This F4. . $\mathrm{H} 9 A$ interaction is the shortest of the F $\cdots$. H interactions present with two other weaker F...H interactions of 2.49

Symmetry codes: (ii) $-x+\frac{1}{2}, y,-z$; (iii) $x,-y+\frac{1}{2}, z-\frac{1}{2}$; (iv) $-x+\frac{1}{2}, y-\frac{1}{2}, z$; (v) $-x+\frac{1}{2},-y+\frac{1}{2},-z+\frac{1}{2}$; (vi) $-x+1, y-\frac{1}{2},-z+\frac{1}{2}$; (vii) $x,-y+1,-z+\frac{1}{2}$.
( $\mathrm{F} 1 \cdots \mathrm{H} 10 A$ ) and $2.64 \AA$ ( $\mathrm{F} 1 \cdots \mathrm{H} 9 A$ ) to cyclohexyl H atoms. There are also several interactions between pyrdidyl ring H atoms and carboxylate O atoms from neighboring cations, i.e. a $2.408 \AA$ interaction with Co-bound oxygen O1, and a $2.700 \AA$ interaction with terminal oxygen O 2 . The short interaction has a $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ angle of $140.7^{\circ}$ so it does not appear in Table 3. There also exists $\pi-\pi$ stacking for each of the two pyridyl rings with neighboring cations stacked antiparallel. Each has a distance of 3.829 (13) A between ring centroids.

## 4. Database survey

There is very little information in the literature about $\mathrm{H}_{2} \mathrm{bpcd}$ and its metal complexes. There is a structurally characterized heptacoordinate $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathrm{H}_{2}\right.\right.$ bpcd $\left.)\left(\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}\right)\right]\left(\mathrm{ClO}_{4}\right)_{2}$ complex with trans pyridine N atoms and cis carboxylic acid groups (Oddon et al., 2012). In that case, $\mathrm{Fe}^{\mathrm{II}}$ is coordinated in a distorted pentagonal-bipyramidal geometry with an unusual $\mathrm{N}_{4} \mathrm{O}_{3}$ donor atom set, including a bound acetone molecule. The carboxylic acid moieties are fully protonated with the $\mathrm{H}_{2} \mathrm{bpcd}$ ligand coordinating through the carbonyl O atoms, which reside in the equatorial plane. The coordinating amine N atoms also lie in this plane, whereas the pyridyl N atoms are coordinating at the axial positions. This unique arrangement results in longer $\mathrm{Fe}-\mathrm{O}$ and $\mathrm{Fe}-\mathrm{N}_{\mathrm{py}}$ bonds than are typically observed. In the present case, a fully deprotonated bpcd ${ }^{2-}$ ligand binds $\mathrm{Co}^{\mathrm{III}}$ in a pseudo-octahedral fashion with trans acetate groups to form a hexacoordinate complex.

Although only one structure of a metal- $\mathrm{H}_{2} \mathrm{bpcd}$ complex has been reported in the literature, there are several structures reported for related pseudo-octahedral $\mathrm{Co}^{\mathrm{III}}$ complexes with bis-2-pyridylmethyl substituted diamino diacetic acids, i.e. $\mathrm{H}_{2}$ bped (A) and $\mathrm{H}_{2}$ bppd (D) in Fig. 1. We previously reported the structure of $[\mathrm{Co}(\mathrm{bppd})] \mathrm{PF}_{6}$ (McLauchlan et al., 2013), and there are two structural reports for the $[\mathrm{Co}(\mathrm{bped})]^{+}$complex ion with different counter-ions, e.g. $\mathrm{BF}_{4}{ }^{-}$and $\mathrm{PF}_{6}{ }^{-}$(Mandel \& Douglas, 1989; Caravan et al., 1997a). In these cases, the $\mathrm{Co}^{\mathrm{III}}-$

bppd $^{2-}$ and $\mathrm{Co}^{\text {III }}-$ bped $^{2-}$ complexes form similar hexadentate structures with acetate O atoms in a trans orientation and pyridyl N atoms in a cis orientation.

## 5. Synthesis and crystallization

$\mathrm{H}_{2} \mathrm{bpcd}(\mathrm{C})$ was prepared from trans-1,2-diaminocyclohexane using the procedure reported for $\mathrm{H}_{2} \mathrm{bppd}$ (D) (Kissel et al., 2014). The title compound was prepared using methods analogous to those previously reported for $[\mathrm{Co}(\mathrm{bppd})] \mathrm{PF}_{6}$ (McLauchlan et al., 2013). Crystals suitable for diffraction were isolated by slow evaporation of a saturated acetonitrile solution (yield: $120 \mathrm{mg}, 0.20 \mathrm{mmol}, 40 \%$ ).

Analysis observed (calculated) for $\mathrm{CoC}_{22} \mathrm{H}_{28} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{PF}_{6}$ : C 42.56 (43.00), H 3.85 (4.26), N 8.94 (9.11). IR ( $\left.v \mathrm{~cm}^{-1}, \mathrm{KBr}\right)$ : 3048 ( $m, \mathrm{C}-\mathrm{H}$ aryl str), 2945 ( $m, \mathrm{CH}_{2}$ str), 1665 ( $\mathrm{vs}, \mathrm{COO}^{-}$ $\operatorname{str}), 1612$ ( $m$, py str), 1477 ( $w$, py str), 1445 ( $m, \mathrm{CH}_{2}$ def), 1384 ( $s, \mathrm{COO}^{-}$str).

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. The structure of the title complex can be solved and refined in $I b c a$ with well-separated cations and anions. There is a small amount of disorder that can be modelled for the $\mathrm{PF}_{6}{ }^{-}$anion. F2 and F3 can be moved in the plane. $R 1$ can be reduced to 0.0252 by modeling this disorder,
but the occupancy is less than $10 \%$ and results in a less chemically satisfactory $\mathrm{PF}_{6}{ }^{-}$anion. Therefore, the disorder was not modelled. All H atoms were placed geometrically $(\mathrm{C}-\mathrm{H}=0.93-0.97 \AA)$ and refined using a riding model.

# Crystal structure of $\left\{2,2^{\prime}-\left[N, N^{\prime}\right.\right.$-bis(pyridin-2-ylmethyl)cyclohexane-trans-1,2diyldi(nitrilo)]diacetato\}cobalt(III) hexafluoridophosphate 

Craig C. McLauchlan, Daniel S. Kissel and Albert W. Herlinger

## Computing details

Data collection: APEX2 (Bruker, 2008); cell refinement: SAINT (Bruker, 2008); data reduction: SAINT (Bruker, 2008); program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL2014 (Sheldrick, 2015); molecular graphics: ORTEP-3 for Windows (Farrugia, 2012); software used to prepare material for publication: enCIFer (Allen et al., 2004) and publCIF (Westrip, 2010).
$\left\{2,2^{\prime}-\left[N, N^{\prime}\right.\right.$-Bis(pyridin-2-ylmethyl)cyclohexane-trans-1,2-diyldi(nitrilo)]diacetato\}cobalt(III) hexafluoridophosphate

## Crystal data

$\left[\mathrm{Co}\left(\mathrm{C}_{22} \mathrm{H}_{26} \mathrm{~N}_{4} \mathrm{O}_{4}\right)\right] \mathrm{PF}_{6}$
$M_{r}=614.37$
Orthorhombic, Ibca
$a=13.9848$ (4) $\AA$
$b=14.6221$ (4) $\AA$
$c=22.2177(6) \AA$
$V=4543.2(2) \AA^{3}$
$Z=8$
$F(000)=2512$

## Data collection

Bruker APEXII
diffractometer equipped with a CCD detector
Radiation source: fine-focus sealed tube
Graphite monochromator
Detector resolution: 8.3333 pixels $\mathrm{mm}^{-1}$
$\varphi$ and $\omega$ scans
Absorption correction: multi-scan
(SADABS; Bruker, 2008)
$T_{\text {min }}=0.691, T_{\text {max }}=0.834$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.027$
$w R\left(F^{2}\right)=0.079$
$S=1.12$
3630 reflections
174 parameters
0 restraints
$D_{\mathrm{x}}=1.796 \mathrm{Mg} \mathrm{m}^{-3}$
Mo $K \alpha$ radiation, $\lambda=0.71073 \AA$
Cell parameters from 9742 reflections
$\theta=2.7-31.0^{\circ}$
$\mu=0.92 \mathrm{~mm}^{-1}$
$T=100 \mathrm{~K}$
Parallelipiped, translucent dark red
$0.44 \times 0.36 \times 0.21 \mathrm{~mm}$

57644 measured reflections
3630 independent reflections
3401 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.017$
$\theta_{\text {max }}=31.0^{\circ}, \theta_{\text {min }}=1.8^{\circ}$
$h=-20 \rightarrow 20$
$k=-21 \rightarrow 21$
$l=-32 \rightarrow 32$

Primary atom site location: structure-invariant direct methods
Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from neighbouring sites
H -atom parameters constrained

```
\(w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0415 P)^{2}+5.6191 P\right]\)
    where \(P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3\)
\((\Delta / \sigma)_{\text {max }}=0.001\)
```

$$
\begin{aligned}
& \Delta \rho_{\max }=0.66 \mathrm{e} \AA^{-3} \\
& \Delta \rho_{\min }=-0.52 \mathrm{e} \AA^{-3}
\end{aligned}
$$

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger. There is a small amount of disorder that can be modeled for the $\mathrm{PF}_{6}$ anion. F2 and F3 can be moved in the plane, as one might imagine. R1 can be reduced to 0.0252 by modeling it, but the occupancy is less than $10 \%$ and results in a less chemically satisfactory $\mathrm{PF}_{6}$ anion. Therefore, the disorder was not modeled.
